

AN
ELEMENTARY; PRACTICAL AND
THEORETICAL
TREATISE ON NAVIGATION:

WITH A
NEW AND EASY PLAN

FOR FINDING
DIFF. LAT., DEP., COURSE, AND DISTANCE BY PROJECTION.

BY M^r F. MAURY,
LIEUT., U. S. NAVY.

SECOND EDITION, REVISED AND CORRECTED.

PHILADELPHIA:
EDWARD C. BIDDLE, NO. 6 SOUTH FIFTH STREET.
1843.

NOTICES
OF FIRST EDITION OF
MAURY'S NAVIGATION.

“U. S. N. S., New York, January 19, 1836.

“Dear Sir,—I have had much pleasure in the perusal of your “New Theoretical and Practical Treatise on Navigation;” the plan and arrangements of which are original; it contains little or nothing superfluous, and every part of it appears to be as clear and intelligible as the nature of the subject will admit. Such a work has long been wanted in our Naval Schools, and on board our vessels of war. I intend to make use of it in the Naval School on this station; and I recommend it to be used by all the professors of Mathematics, and Nautical Science in the Navy of the United States.

Yours respectfully,

EDW. C. WARD.

“Passed Midshipman M. F. Maury.
U. S. Navy.”

Prof. Math. U. S. Navy.”

“U. S. Navy Yard, Gosport, March 7, 1836.

“I have examined a Treatise on Navigation written by M. F. Maury of the U. S. Navy; and have no hesitation in recommending it to the students of that science. The explanations are clear, the rules are illustrated by many examples, and the new arrangement of some of the tables exemplify the calculations of the navigator. Mr. Maury is deserving of great credit for the work, and I wish him every success.

P. J. RODRIGUEZ.

“Navy Department, April 9, 1836.

“Sir,—I have to request that you will add the “New Theoretical and Practical Treatise on Navigation,” by M. F. Maury, Passed Midshipman, to the list of books furnished vessels of the navy going to sea.

I am respectfully yours.

(Signed,) M. DICKERSON.”

“COM. JOHN RODGERS,
President of the Board of Navy Commissioners.”

Entered according to Act of Congress, in the year 1836, by
KEY & BIDDLE,
In the Clerk's Office of the District Court of the Eastern District of Pennsylvania.

PREFACE.

THE object of the present volume, is to place in the hands of students, and especially of the Midshipmen of the United States Navy, a Text Book, in which the theory as well as the practice of Navigation, is explained and taught.

It is not pretended that new theories are set forth, or that new principles are established in this work; but it is believed that those which have already been established, are here embodied in such a form, that the means of becoming a theoretical as well as a practical navigator, are placed within the reach of every student.

For this purpose the works of Bonnycastle, Colburn, Hutton, Legendre, Davies, Bowditch, Lardner, Hassler, Kelly, Keith, and La Place, have been consulted.

Care has been taken to introduce only those theorems upon which the problems in Navigation immediately depend, and which it is necessary to understand, in order, satisfactorily to comprehend the principles of Mathematics and Astronomy, involved in the solution of these problems.

The fear of introducing more than is essentially requisite for this purpose, may have led to an error on the other extreme, by causing something to be omitted, which should have been inserted; but if such a fault be detected in the work, while it will be readily admitted on one hand to be a fault, it can scarcely be unjust on the other, to say that the error is on the safe side; especially when they who judge, are reminded, that there is not throughout the whole work, a single principle laid down which does not serve at once as a rule, or as the basis of a rule, or as reference in some succeeding demonstration, position, or explanation either to prove, establish, or elucidate; and moreover, that there are many, (perhaps the greater number,) of those for whose benefit the work is chiefly designed, who, during the whole period of their service at sea, never have the advantage of instruction from a teacher of Navigation; consequently they have to depend upon their own exertions, and the books before them, for their proficiency as Navigators. How necessary is it then, that the work on Navigation for them, should be an elementary one, adapted to the capacity of all, and that it should not embrace the widest range; more particularly so, as there is not yet any regular system of education provided for the Navy.

The idea of such a work as the present, grew out of the author's own experience, and was suggested to him by his own wants while

a student of Navigation ; if it be not sufficient for the supply of similar wants on the part of others, it is hoped that it will, at least, serve to provoke some more capable pen to undertake and complete what is here attempted.

A more elementary work than any hitherto published on Navigation is much required as a school book in the United States. The attention of teachers of Navigation throughout the country is respectfully invited to it.

These pages were written chiefly on board of a man-of-war, in the midst of the various calls of duty, and the thousand interruptions incident to such a place ; the author trusts that this circumstance will ensure him on the part of his brother officers, and those into whose hands his work may fall, the indulgence usually claimed for inexperienced authors.

ALGEBRA.

B

ALGEBRA.

§ I. **ALGEBRA** is a method of computation, in which magnitudes, or quantities, are represented by means of the letters of the alphabet. These letters have no positive or fixed value; they only stand for the quantities to be computed.

§ II. In algebra, known quantities are expressed either according to their numerical value, or by the first letters *a, b, c, etc.*, of the alphabet.

§ III. And quantities of unknown value are usually represented by the last letters, *x, y, z, etc.*

§ IV. In algebraical computations, certain characters, called *signs*, have been introduced, and are used in the place of written words: thus,

+ (*plus*) is the sign of addition.

− (*minus*) is the sign for subtraction.

× or . is the sign for multiplication.

= is the sign of equality.

÷ is the sign for division.

$a + b - c \times d = x + y$, or $\frac{x}{y}$, is read *a plus b minus c multiplied by d equals x divided by y.*

§ V. $a > b$ signifies that the former quantity (*a*) is greater than the latter (*b*).

$a < b$ signifies that the latter quantity (*b*) is greater than the former (*a*).

§ VI. (*:*) is to (*:*) as, represents equality of ratio, and denotes proportion: thus $a : b :: c : d$, (read *a is to b as c is to d*), signifies that the ratio of *a* to *b* is equal to the ratio of *c* to *d*, and that these four quantities are proportional.

§ VII. ∽ represents the difference between any two unknown quantities between which it is placed; thus, $x \smile y$ denotes the difference between *x* and *y*.

§ VIII. ∞ signifies that the quantity standing before it, thus, $x \infty$, is infinite in value.

§ IX. The numbers 2, 3, 4, etc., placed after a letter, thus, a^2 , a^3 , a^4 , denotes the 2d, 3d, 4th, etc., power of the quantity which that letter represents. The second power is the *square*, the 3d the *cube*, the 4th the *biquadrate*:

$$a \times a = a^2,$$

$$a^2 \times a = a^3,$$

$$a^3 \times a = a^4.$$

§ X. The numbers 2, 3, 4, etc., placed as above, are called the *indices* of the quantities to which they are affixed.

§ XI. The quantity which is a constant multiplier in the involu

tion of a power, is called the root of that power: thus, (§ IX.,) a is the cube root of a^3 , and the square root of a^2 .

§ XII. $\sqrt{\quad}$ is called the *radical* sign; and \sqrt{x} , or $\sqrt[3]{x}$, also $x^{\frac{1}{2}}$, denotes that the square root of x is the quantity alluded to; so $\sqrt[3]{y}$, or $y^{\frac{1}{3}}$, denotes the cube root of y : and so on with the other numbers, or with letters thus placed.

The number or letter placed over the radical sign, thus, $\sqrt[4]{\quad}$, $\sqrt[5]{\quad}$, or placed thus, $x^{\frac{1}{4}}$, etc., is called the exponent.

§ XIII. A *surd* is a quantity to which the radical sign ($\sqrt{\quad}$) is prefixed, and whose root cannot be expressed by numbers; thus, $\sqrt{3}$, $\sqrt[3]{5}$, are surds.

§ XIV. A *term* is any quantity that is separated from another by a sign; thus, a , b and x , are terms in the compound quantity $a + b - x$.

§ XV. The number, (5,) or the letter, (c,) that is prefixed to any quantity, (5 a , or $c a$,) is called the *coefficient* of that quantity.

§ XVI. *Like quantities* consist of the same letters as $a b + 4 a b - 2 a b$.

§ XVII. *Unlike quantities* consist of different letters, as $x + 2 y \times a + b$.

§ XVIII. When a quantity has no sign prefixed to it, +, or plus, is understood.

§ XIX. $\sqrt{x^2 + y}$, or $(x^2 + y)^{\frac{1}{2}}$, denotes that these two quantities are as one, and that the square root of their *sum* is alluded to by the radical sign, or the exponent $\frac{1}{2}$. Thus, the square root of $64 + 36$, or $\sqrt{64 + 36}$, is $8 + 36 = 42$, but the square root of $64 + 36$, or $(64 + 36)^{\frac{1}{2}}$, under a *vinculum*, is 10, for $64 + 36 = 100$, and the square root of 100 is 10.

§ XX. Addition is performed by collecting several quantities in a more simple form: $3 a + 10 a + a = 14 a$, (read *fourteen times a*). 1 is understood to be the coefficient of every quantity that has no coefficient prefixed to it.

§ XXI. When the quantities to be cast up have unlike signs, the problem is solved, partly by addition and partly by subtraction. If the *negative* be greater than the *positive* quantities, the negative sign must be retained in the result. The sum of $6 - 10 + 9$, is 5; for 6 and 9 are here positive quantities, and make 15; and $15 - 10 = 5$: and the sum of $6 - 10 - 9$, is -13 ; for $-10 - 9 = -19$; and $-19 + 6$, or $6 - 19 = -13$. Every quantity, which has not a sign prefixed to it, is understood to be positive.

To add together, $4 x - 9 x + x + 3 x - 5 x$. Collecting all the positive quantities into one sum, and all the negative quantities into another, then taking the less from the greater, the remainder, (prefixing the sign of the greater,) is the answer. Thus:

$$\begin{array}{r}
 4 x - 9 x \\
 \quad x - 5 x \\
 3 x \\
 \hline
 8 x - 14 x = -6 x
 \end{array}$$

$$\begin{array}{r}
 -6ay^2 \\
 4ay^2 \\
 9ay^2 \\
 \hline
 \text{Ans. } 7ay^2
 \end{array}
 \qquad
 \begin{array}{r}
 10ba \\
 2ba \\
 -19ba \\
 \hline
 -7ba
 \end{array}
 \qquad
 \begin{array}{r}
 -ac \\
 7ac \\
 -9ac \\
 \hline
 -3ac
 \end{array}$$

§ XXII. If all the terms be not *like* quantities, the positive and the negative of those that are like must each be added up separately; then these two sums must be subtracted, the one from the other, and the remainder thus obtained, connected by its proper sign to the *unlike* quantities, shows the answer. To add together:

$$\begin{array}{r}
 4x + 6a - c^2 + 9y \\
 -10x - 5a + c^2 - 5y \\
 x - a + 4c^2 + 3y \\
 2x + 2a \\
 \hline
 -3x + 2a + 4c^2 + 7y
 \end{array}$$

The positive x 's are, $4x + x + 2x = 7x$; the negative are, $-10x$. The difference is, $(7x - 10x =)$, $-3x$. The positive a 's are, $6a + 2a = 8a$; the negative are, $-5a - a = -6a$. The difference is, $(8a - 6a =)$, $2a$. The positive c^2 's are, $c^2 + 4c^2 = 5c^2$; the negative is, $-c^2$. The difference is, $(5c^2 - c^2 =)$, $4c^2$. The positive y 's are, $9y + 3y = 12y$; and the negative are, $-5y$. The difference is, $(12y - 5y =)$, $7y$.

To add together:

$$\begin{array}{r}
 \sqrt{ab - a^2 + 2xy - 6x + 10a^2 - 9xy - a^2b + y - a} \\
 -\sqrt{6ab + 3a^2 + \sqrt{5ab - x + xy + a^2b - 4xy - 2x} \\
 a - c^2 + 4y - \sqrt{2ab - 2a^2 - 3xy + 4x + 14xy + a^2b} \\
 \sqrt{ab - a^2 + 2xy + 6x - a^2b + a - c^2 + 4y} \\
 -\sqrt{6ab + 10a^2 - 9xy - x - 2a^2b + a + y} \\
 \sqrt{5ab + 3a^2 + xy - 2x + a^2b} \\
 -\sqrt{2ab - 2a^2 - 4xy + 4x} \\
 \qquad \qquad \qquad -3xy \\
 \qquad \qquad \qquad 14xy \\
 \hline
 -\sqrt{4ab + 20a^2 + 2xy + 2x - a^2b + 2a - 2c^2 + 10y}
 \end{array}$$

To add together:

$$\begin{array}{r}
 y + ab + dx^3 - z^3a \\
 y + cb + bx^3 - z^3x \\
 \hline
 2y + (a+c)b + (d+b)x^3 - z^3(a+x)
 \end{array}$$

To add together:

$$\begin{array}{r}
 a + b + c - x \\
 2a - b - 2c - 2x \\
 -a + ab - c - 4x \\
 \hline
 2a + ab - 2c - 7x
 \end{array}$$

§ XXIII. Subtraction is the reverse of addition. The method of performing it consists in changing, or reversing, all the signs of the subtrahend, (i. e., making the positive negative, and the reverse,) and then proceeding as in addition; viz., by adding together like quantities that have like signs; and subtracting from each other like quantities that have unlike signs. The quantity or the quantities that result from this operation is the remainder.

To subtract $a - b$ from $a + b$.

$$\begin{array}{r} \text{Changing the signs of the subtrahend} \quad \begin{array}{r} a + b \\ a - b \\ \hline \end{array} \\ \text{The remainder} \quad \underline{\underline{= 2b}} \end{array}$$

This will be readily understood by ascribing a numerical value to a and b . Let $a = 6$ and $b = 4$; now subtract $6 - 4$ from $6 + 4$; $6 - 4 = 2$, and $6 + 4 = 10$, and $10 - 2 = 8$ (or twice $4 = 2b$.)

To subtract $a + b$ from $a - b$.

$$\begin{array}{r} a - b \\ a + b \\ \hline - 2b \\ \hline \end{array}$$

To subtract :

$$\begin{array}{r} 2xy + b^2c - 3a \\ xy - b^2c + a \\ \hline xy + 2b^2c - 4a \\ \hline \end{array}$$

To subtract :

$$\begin{array}{r} 10x - y - ac \\ - 3x - 2y - 4ac \\ \hline 13x + y + 3ac \\ \hline \end{array}$$

§ XXIV. In the multiplication of letters, the product of any two factors is obtained and expressed by prefixing, as coefficients, the several letters contained in the multiplier, to those of the multiplicand. Thus:

$$\begin{array}{r} x + y \\ \text{by } a + b \\ \hline ax + ay + bx + by \\ \hline \end{array}$$

§ XXV. Multiplication is denoted thus, $a \times b$; or thus, $a \cdot b$; or thus, ab .

† 1. By recollecting that a times b , and b times a , are expressions for the same product, just as 4 times 9, and 9 times 4, express the same number, it will at once be understood how there is no difference in the value of the quantity, whether it be expressed ab , or ba . But when several letters are contained in the same term, as $a \times c \times b$, it is generally expressed by the letters arranged in alphabetical order; thus, abc .

§ XXVI. To multiply $x + y$ by $a - b$. Ans. $ax + ay - bx - by$.

When terms of *unlike* signs are multiplied together, their product is negative, and (—) must be prefixed to it.

§ XXVII. The product of $x + y$ by $x + y$ is $x^2 + 2xy + y^2$, or $xx + xy + xy + yy$. The former, being the shorter method of writing it, is the better. The small figures that are affixed show how many times the letter with which they are connected enters as a factor in the term.

§ XXVIII. The product of $x + y$ by $-x - y$, is $-x^2 - 2xy - y^2$.

§ XXIX. The product of $x + y$ by $x - y$, is $x^2 - y^2$; for xy occurring twice in the product, and with unlike signs, (+ and —), cancels itself.

$$\begin{array}{r}
 \text{To multiply } x^2 - y^2 + 3xy \\
 \text{by } \quad \quad \quad x + y \\
 \hline
 x^3 - xy^2 + 3x^2y \\
 \quad \quad \quad x^2y - y^3 + 3xy^2 \\
 \hline
 x^3 + 2xy^2 + 4x^2y - y^3
 \end{array}$$

§ XXX. Unless the quantity be under a vinculum, the index applies only to that letter with which it is in juxta-position. The term xy^2 denotes the product of x and y^2 ; and x^2y denotes the product of the two factors x^2 and y . The term $(xy)^2$, or $\overline{xy^2}$, denotes the square of the product of the two factors x and y . Let $x = 4$ and $y = 3$: $x^2 = 16$ and $y^2 = 9$. The value then of the first term (xy^2) is $4 \times 9 (= 36)$; of the second, (x^2y), it is $16 \times 3 (= 48)$; and of the third, ($\overline{xy^2}$), it is the square of the product, (12), of 3 and 4, ($= 144$).

$$\begin{array}{r}
 \text{To multiply } ax + ab - a^2 \\
 \text{by } \quad \quad \quad a + x + b \\
 \hline
 a^2x + a^2b - a^3 \\
 \quad \quad \quad ax^2 + abx - a^2x \\
 \quad \quad \quad \quad \quad \quad abx + ab^2 - a^2b \\
 \hline
 ax^2 - a^3 + 2abx + ab^2
 \end{array}$$

$$\begin{array}{r}
 \text{To multiply } -5a - 4x \\
 \text{by } \quad \quad \quad 2 - a - x \\
 \hline
 -10a - 8x \\
 \quad \quad \quad 5a^2 + 4ax \\
 \quad \quad \quad \quad \quad \quad 5ax + 4x^2 \\
 \hline
 -10a + 5a^2 - 8x + 9ax + 4x^2
 \end{array}$$

§ XXXI. When the same letter enters into both factors, the product is obtained by adding the indices or exponents of the letter, as $a^3 \times a^2 = a^5$; for $3 + 2$ is 5. And $x \times x$ is x^2 ; 1 is the index and coefficient of every letter which has no other index or coefficient expressed.

§ XXXII. Division is the converse of multiplication.

4 times b divided by 4 gives b . So a times b divided by a gives b .

$$\begin{array}{r}
 4ax \div 2x = 2a \\
 4ax \div 2a = 2x
 \end{array}$$

§ XXXIII. Division being the converse of multiplication, the product of the divisor by the quotient gives the dividend. Thus, $2x \times 2a = 4ax$.

§ XXXIV. When the dividend and divisor are powers, or are roots, of the same quantity, the index, or exponent, of the divisor, minus that of the dividend, is the quotient. Thus, $x^3 \div x^2 = x$; $x^5 \div x^2 = x^3$.

§ XXXV. When all the terms of the dividend have letters that are common to the divisor, the operation of dividing is performed

by striking out from the dividend the letters of the divisor, and dividing the coefficients. Thus,

$$\begin{aligned} 8xy + 2y &= 4x \\ 12axz + 3ax &= 4z \\ 6xy^2z + 2xy &= 3yz. \end{aligned}$$

§ XXXVI. Division is sometimes expressed without being performed, as $x + y + a$, or $\frac{x+y}{a}$.

§ XXXVII. This last quantity is a fraction. Fractions in algebra are multiplied, divided, etc., after the same manner by which such operations are performed in common arithmetic.

§ XXXVIII. Two or more quantities, with the sign (=) of equality between them, constitute an equation; as $x + 10 = 14 + 6$.

§ XXXIX. All the quantities or terms that are on either side of the sign (=) constitute a *member* of the equation; $x + 10$ is the *first*, and $14 + 6$ is the *second*, member of the equation $x + 10 = 14 + 6$. The two members, necessarily, are always equal to each other.

§ XL. In the process of solving, or reducing, an equation, the known quantities, or terms, of the equation, are all collected and arranged with their proper signs, in one member of the equation, and the unknown quantities in the other member, as $x = 14 + 6 - 10$. The value of x in this equation, is therefore equal to 10.

§ XLI. In transposing a term from one member to another, the equality of the two members of the equation is preserved, by *changing the sign* of the term transposed. By transposition, *positive* terms become *negative*, and the reverse; also the sign (\times) of multiplication becomes (\div) the sign of division, and vice versa. Thus, in the equation above $x + 10 = 20$, (or $6 + 14$;) by transposition, $x = 20 - 10$. Also, in the equation $12 \times 4 = 8 \times 6$, by transposing we have $\frac{12}{8} = \frac{6}{4}$; and the equation $a + b = x + y$, by transposition, becomes $a \times y = x \times b$.

To find the value of x in the equation $a + x - c = b + 14$; by transposing a and $-c$, and changing their signs, the value of x is obtained: it stands thus, $x = b + 14 - a + c$.

Ex. $a - x^2 + y = 90 + a - 40$. To find y ; a being in each member, and having the same sign, cancels itself, and may therefore be stricken from the equation; for if transposed, the expression would be $a - a$, which two balance each other. The value of y is obtained then, by transposing $-x^2$, when the equation stands thus, $y = 90 - 40 + x^2$; in its most simple form, thus, $y = 50 + x^2$.

Ex. $8x - 10 = 80 + 2x$. To find x ; transposing and placing the known and unknown quantities on opposite sides, the equation stands, $8x - 2x = 80 + 10$. Subtracting and adding, it becomes $6x = 90$; and $x = 15$, (by division).

Ex. $x + 2 + 10 = 14 + 8$. To find x ; $\frac{x}{2}$ or $\frac{x}{2} = 14 + 8$

—10. The value of the second member of the equation is 12; therefore $\frac{x}{2} = 12$; and by multiplication, $x = 24$.

From the two last examples, this general conclusion may be drawn, viz.:

§ XLII. When a multiplier of either member is transposed, it becomes divisor to the other member; and vice versâ.

Ex. $8x^2 + ax - 10x = 14x + 4x^2 + 16x$. To find x . x is common in every term of each member of the equation. Then, dividing by x , the equation becomes $8x + a - 10 = 14 + 4x + 16$; transposing and placing all the x terms alone in one member, $8x - 4x = 14 + 16 + 10 - a$; subtracting and adding, $4x = 40 - a$; dividing, $x = 10 - \frac{a}{4}$.

Ex. $3bx - 9ab = 3y$. To find x . Transposing, $3bx = 3y + 9ab$; dividing, $x = \frac{3y + 9ab}{3b} = \frac{y}{b} + 3a$. Therefore, $x = \frac{y}{b} + 3a$.

Ex. $\frac{x}{3} + \frac{x}{2} = 10$. To find x . Clearing the equation of fractions; 1st, $x + \frac{3x}{2} = 30$; 2d, $2x + 3x = 60$; adding, $5x = 60$; dividing, $x = 12$.

§ XLIII. Thus an equation is cleared of fractions *by multiplying every term (except the fraction itself) by the denominator*.

Ex. 1. The commander of a man-of-war is desirous of having his ship calked, that he may proceed on his voyage. His own calkers can finish the job of calking in 10 days. But he employs a gang from the shore, that could finish the whole work in 6 days, to assist his. How many days' job are there for both gangs together?

Let x denote the job of work. Then $\frac{x}{10}$ is one day's work for the ship's calkers; $\frac{x}{6}$ is one day's work for the shore gang; and $\frac{x}{10} + \frac{x}{6} = 1$ day's work for both gangs together. Clearing this equation of fractions, $6x + 10x = 60$; and $16x = 60$, or $x = 3\frac{3}{4}$, the number of days.

Ex. 2. A vessel, after an engagement, could muster only 238 able bodied men; on examining her list of sick and wounded, she found her loss in killed to be $\frac{1}{3}$ of her whole crew, and in wounded $\frac{1}{4}$ of the whole crew. What crew had she when she went into action?

Let x denote her crew when the action commenced. Thus, $\frac{x}{5} + \frac{x}{3} + 238 = x$. Clearing the equation of fractions, $3x + 5x + 3570 = 15x$; transposing, $3570 = 7x$, or $510 = x$, the whole crew when the action commenced.

§ XLIV. When the value of more than one unknown quantity is required, the problem, if definite, comprises conditions for as many equations as there are quantities required. In such cases the unknown quantities (x, y, z , etc.) have the same value in all the equations; i. e. x in one equation is equal to x in another of the same set. When the value of x, y , or z , is found, its value is substituted in its stead.

Ex. $x + y = 44$
 $x - 3y = 36$ } To find x and y ; $x = 44 - y$, and $x = 36 + 3y$; thus $44 - y = 36 + 3y$; transposing, $4y = 8$, or $y = 2$; and substituting, $x = 44 - y$, or $x = 42$.

Ex. $x + y + z = 60$
 $x + 4y + 3z = 144$
 $2x + y + 8z = 132$ } To find x, y , and z ; $x = 60 - y - z$; $x = 144 - 4y - 3z$; and $x = 66 - \frac{y}{2} - 4z$. Eliminating x ; $60 - y - z = 144 - 4y - 3z$; and $144 - 4y - 3z = 66 - \frac{y}{2} - 4z$. Transposing, to find the value of y ; $3y = 144 - 60 - 2z$, or $y = 28 - \frac{2z}{3}$; again, $7y = 288 - 132 - 8z + 6z$, or $y = \frac{156 - 2z}{7}$; eliminating y , $28 - \frac{2z}{3} = \frac{156 - 2z}{7}$; clearing the equation, $14z - 588 = 468 - 6z$; transposing, $20z = 120$ or $z = 6$.

For z , in the equation $y = 28 - \frac{2z}{3}$, substituting its value (6), $y = 28 - \frac{12}{3}$, or $y = 24$. And for z and y , in the equation $x = 60 - y - z$, substituting their values (24 and 6), $x = 60 - 24 - 6$, or $x = 30$.

§ XLV. There is another manner of expressing certain equations which do not involve more than 4 terms, and when thus expressed the terms are said to be *proportional*. Thus the proportion $3 : 4 :: 6 : 8$, is but another method of expressing the equation $3 + 4 = 6 + 8$, or $\frac{3}{4} = \frac{6}{8}$. The dots ($:$) being an abbreviation of the sign ($+$) of division; and the dots ($::$) being another form for expressing the sign ($=$) of equality, to show that the *ratio* between the quantities on each side of it is the same.

§ XLVI. Whence it may be inferred as a general rule, that, if the *quotient of two quantities be equal to the quotient of two others*, these four quantities are proportional. And,

† 1. That the ratio between either divisor and its dividend, is equal to the ratio between the other divisor and its dividend.

§ XLVII. By this rule we have $4 : 3 :: 8 : 6$, for $\frac{4}{3} = \frac{8}{6}$. This form of expression for the proportion ($3 : 4 :: 6 : 8$) first quoted, is called "*invertendo*," (from inverting the divisor and dividends,) thus $3 + 4 = 6 + 8$, and *inversely* $4 + 3 = 8 + 6$.

§ XLVIII. By the same rule we also have $3 : 6 :: 4 : 8$. This form of expression for the proportion ($3 : 4 :: 6 : 8$) is called

“*alternando*,” for by taking the terms *alternately* we have $3 \div 6 = 4 \div 8$.

§ XLIX. Whence also another general rule in proportions: that, if four quantities be proportional, they are also proportional when taken *inversely*, or when taken *alternately*.

§ L. $3 \div 4 = 6 \div 8$, by transposition $3 \times 8 = 6 \times 4$; wherefore, also, if the product of two factors be equal to the product of two other factors, those four factors are proportional, as $3 : 6 :: 4 : 8$.

GEOMETRY.

PART I.

GEOMETRY.

DEFINITIONS.

- § 1. *A point* is an atom of space.*
§ 2. *A line* (——) is length without breadth.
§ a. The track of a moving point would be a line.
§ b. The extremities of every line are points.
§ c. A line may be of any length.
§ d. Lines are either straight or curved.
§ 3. *A straight* or *right line* (——) is the shortest line that can be drawn from one point to another.

§ a. If two lines meet each other they form an angle.

§ 4. *A plane* is an extent, (as the surface of this page), on which the straight line will lie that joins any two points which are in that extent.

§ a. A plane is without thickness, and it may be of any length and breadth.

§ b. The limits of every plane are lines.

§ c. If two planes cross each other, the line of their intersection is a straight line.

§ 5. Two lines diverging from, or meeting in, the same point, form an *angle*.

§ a. The point in which the lines join or cross each other, is called the *angular point*.

§ b. Angles are either right, acute, or obtuse.

§ 6. When one straight line stands upon another, without inclining to either side, the angle, or angles, which these two lines form, are called *right angles*.

§ a. All right angles are equal, and every one contains 90° (*degrees*). (Vide § 49, § d.)

* According to the *atomic* theory of matter, all bodies are composed of indivisible and impenetrable particles, called atoms; an atom then is to matter what a point is to space; hence the idea of an atom of space.

§ *b*. Straight lines that form right angles with each other, are said to be *perpendicular* the one to the other; and those that are perpendicular are at right angles with each other.

§ 7. Every angle which is *less* than a right angle, is an *acute* angle.

§ *a*. Angles are generally particularized by means of letters; as the angle B. But when there are more angles than one at the same angular point, the angle to be particularized is made known by placing the letter at the angular point *between* the letters which stand for the lines that form the angle. As the angle A B C, or C B D.

§ 8. Every angle which is *greater* than a right angle is an *obtuse* angle; as the angle C.

§ *a*. An *oblique* angle may be either acute or obtuse.

§ *b*. Two angles are equal, when they contain the same number of degrees ($^{\circ}$), minutes ($'$), and seconds ($''$), or when the lines which form an angle have the same divergence from each other, which the lines have that form the other angle.

§ *c*. The difference between an oblique angle and a right angle is the *complement* of the oblique angle.

§ 9. *Parallel lines* are lines that have always the same distance between them. They lie in the same direction, and if lengthened, *ad infinitum*, would neither

approach, or recede from, each other.

§ *a*. The distance of two parallel lines from each other is measured by any straight line (*p*) that may be drawn between them, perpendicularly from one to the other.

§ 10. A *figure* is any extent bounded by one or more lines, or surfaces.

§ *a*. The space included by a figure is called its *area*.

§ 11. A *superficies* is the surface of a figure.

§ *a*. A superficies and a plane coincide, when a straight line, that joins any two points in the superficies, lies on that surface. The superficies of a figure is limited to the extent of the surface of that figure; but its plane is infinite.

§ *b*. When the superficies and the plane of a figure coincide, the former is called a *plane* superficies.

§ 12. A *plane triangle* is a figure that is formed by the intersection of three straight lines, any two of which intersect the other in different points.

§ *a*. The intercepted parts of these lines are called the sides of the triangle.

§ b. Every triangle has six parts; viz., three sides, and three angles.

§ c. Triangles, with regard to their sides, are either equilateral, isosceles, or scaline; with regard to their angles, they are either acute, right, or obtuse angled.

§ 13. An equilateral triangle has its sides all equal to each other; viz., b equal to a or c .

§ 14. An isosceles triangle has two equal sides; as, c and a .

§ a. An isosceles triangle may be either acute, right, or obtuse angled. Its third side (b) is its base.

§ 15. A scaline triangle has none of its sides equal.

§ a. A scaline triangle may also be right or oblique angled.

§ 16. An acute angled triangle has each of its angles less than a right angle.

§ a. The vertex of a triangle is the angle that is opposite to the base of the triangle.

§ b. Any angle may be called the vertical angle, and consequently any side may be made the base.

§ 17. A right angled triangle has an angle (B), that is, a right angle.

§ a. The side (b) which subtends the right angle, is called the *hypotenuse*; the two other sides (c and a) are called *legs*.

§ 18. An obtuse angled triangle has an angle (C) that is obtuse.

§ a. The altitude of a triangle is the perpendicular distance (p) of the vertical angle (C) (§ 16, § b.) from the base (c). The base must be produced to meet the perpendicular,

if the perpendicular fall without the triangle.

§ b. As any side (§ 16, § b.) may be made the base of a triangle, the perpendicular distance of any angle from its opposite side may be called the altitude, or height of the triangle.

§ 19. A parallelogram is a right lined (§ 3.) quadrilateral figure, the opposite sides of which are equal and parallel.

§ a. The altitude of a parallelogram is the distance (p) (§ 9. § a.) between either pair of its opposite sides. To show the altitude of a parallelogram, either of two

D

opposite sides may be produced until it meets at right angles, a perpendicular from the other side.

§ b. The measure or *area* of a parallelogram, is the product of its length and breadth, or of its base and altitude.

§ c. Any side of a parallelogram may be made its base.

§ 20. A *square* is a parallelogram of which all the sides and angles are respectively equal.

§ a. Every angle of a square is a right angle.

§ 21. A *rhombus* is a parallelogram that has all of its sides equal to each other; but its angles are not right angles.

§ 22. A *trapezoid* is also a four-sided figure, but only two sides of it are parallel, though they are not equal.

§ a. A *diagonal* is a straight line (*d*) that joins two opposite angles in

a four-sided figure.

§ b. The space included by a parallelogram is called (§ 10. § a.) its *area*, or *measure*, and is expressed (§ 19. § b.) by the product of its base and altitude.

§ 23. Two figures are *equal* when every *part* in one is equal to the part in the other, which corresponds to it; and two equal figures are always of the same magnitude.

§ a. And two figures are of the same *magnitude* when their areas are equal: a triangle and a parallelogram may be of the same magnitude, but they cannot be equal. A triangle only can be equal to a triangle; a parallelogram to a parallelogram, etc.

§ b. Two figures are *similar* when every *angle* in one is equal to the angle which corresponds to it in another figure. Figures only of the same class are similar, viz.: triangles are similar to triangles, parallelograms to parallelograms, etc.

§ c. *Homologous* sides, or angles, are the sides, or angles, which, in two equal or similar triangles, correspond by their relative positions to each other; thus *c* and *f*

are homologous sides, also *b* and *e*, and *a* and *d*.

§ d. Homologous angles are equal to each other. B and E are homologous angles; so also are A and D, and C and F.

AXIOMS.

§ 24. *Axioms* are self-evident truths, such as:

§ a. Things that are equal to the same, or to equal things, are themselves equal.

§ b. If equals be added to, or subtracted from, or substituted for, multiplied or divided by, the same or equal quantities, the sums or remainders, quotients or products, will be equal.

§ c. A part is less than the whole.

§ d. All of the parts are equal to the whole, and the whole to all of its parts.

PROPOSITIONS.

PROPOSITION I.

§ 25. Two straight lines which cross each other, make the two angles that are on the same side of either line, either two right angles, or equal to two right angles.

§ a. Let AB and FG be two straight lines that cross each other in C ; the two angles (FCA, FCB) on the same side of either line (AB) are either two right angles, or are equal to two right angles.

§ b. If AB and FG be perpendicular to each other, they cut each other at right angles (§ 6. § b.); and consequently each of the angles FCA and FCB is a right angle. But if AB and FG be not perpendicular to each other, from C , the point of their intersection, draw CD , which shall be perpendicular to (AB) one of them, then will DCA and DCB , the whole angular space from C , on one side of AB , be two right angles (§ 6. § b.); FCA and FCB , together, also comprehend the same angular space; therefore they are equal to $DCA + DCB$ (§ 24. § c.), which are two right angles. In a similar manner, it may be proven, that $BCF + BCG$, or $GCB + GCA$, or $ACG + ACF$, are equal to two right angles.

PROPOSITION II.

§ 26. All the angles, that any number of straight lines, which cross each other in the same point, make with each other, are together equal to four right angles.

§ a. Since the two angles (§ 25.) FCA, FCB , are equal to two right angles, and also GCB, GCA , equal to two right angles; the four angles FCA, FCB, GCA, GCB , which two straight lines make by crossing each other, are equal to four right angles. If these four angles be divided into any number of other

angles, by straight lines ab, ab , crossing in the point C , the

sum of the divisions thus made will be equal (§ 24. § d.) to four right angles.

PROPOSITION III.

§ 27. When two straight lines $A B$, $D E$, cross each other, they make the angles $D C B$ and $A C E$, or $A C D$ and $B C E$, that are vertically opposite, equal to each other.

§ a. The angles $A C D$ and $D C B$, (§ 25.) are together equal to two right angles; by the same proposition $A C D + A C E$, are also equal to two right angles; wherefore (§ 24. § c.) $A C D + D C B = A C D + A C E$; and $A C D$ is a term in each member of the equation, and being taken away or cancelled, we have (§ 24. § b.) $D C B = A C E$.

§ b. It may be demonstrated in a similar manner, that the vertical and opposite angles $A C D$ and $B C E$, are equal to each other.

PROPOSITION IV.

§ 28. When a straight line ($A C$) crosses two others ($B E$ and $C D$) that are parallel, it makes the angles ($A B E$ and $A C D$), which are on the same side of the two lines, equal to each other.

§ a. If the straight line $A C$ cross the two others perpendicularly, the proposition becomes evident, for the angles formed would be (§ 6. § b.) right angles, and consequently equal.

§ b. But if they cross obliquely, it is obvious that if two lines be parallel to each other, they must have the same divergence from any straight line which crosses them; wherefore (§ 8. § b.) $A B E = A C D$; for $B E$ and $C D$ have the same divergence from $A C$.

§ c. In the same manner it may be shown that $E B f$ is equal to $D C f$.

§ d. The angles ($A B E$, $h B f$, $A C D$, $g C f$, etc.) taken alternately on each side of $A f$, are called *alternate angles*.

§ e. The angles ($A B h$, $A B E$, $f C g$, and $f C D$), on the outside of the two parallel lines are called the *external* or *exterior angles*.

§ f. And the others are called *internal* or *interior angles*.

PROPOSITION V.

§ 29. A right line that crosses two others which are parallel, makes the interior angles (§ 28. § *f.*) ($A H G$ and $D F E$) that are alternate (§ 28. § *d.*) equal to each other.

§ *a.* $A H G$ and $E H B$ are opposite and vertical angles, wherefore (§ 27.) they are equal to each other, and $E H B$ (§ 28.) is equal to $D F E$; therefore (§ 24. § *a.*) $A H G$ is equal to $D F E$.

§ *b.* In the same manner it may be proven that the alternate and interior angles $B H F$ and $C F H$ are equal to each other.

each other.

PROPOSITION VI.

§ 30. If a straight line cross two others that are parallel, it makes the sum of the two internal angles ($B H F$ and $H F C$) that are on the same side of it, equal to two right angles; and the alternate (§ 28. § *d.*) angles ($E H B$, $A H F$, $H F C$, and $D F G$) equal to each other.

§ *a.* The angles $B H E$ and $B H F$ (§ 25.) are together equal to two right angles, and (§ 28.) $B H E$ is equal to $H F C$, therefore (§ 24. § *b.*) the internal angles ($B H F$ and $H F C$) that are on the same side of $E G$, are together equal to two right angles.

§ *b.* The alternate angle $E H B = A H F$, and $H F C = D F G$, because (§ 27.) they are vertically opposite; and (§ 29.) $A H F = H F C$; wherefore (§ 24. § *a.*) the alternate angles $E H B$, $A H F$, $H F C$, and $D F G$, are equal to each other.

§ *c.* After the same manner of demonstration, it may be proven, that the alternate angles $A H E$, $B H F$, $H F D$, and $C F G$, are equal to each other.

§ *d. Cor.* If a straight line ($E G$) cross two others ($A B$ and $D C$) so as to make the sum of the internal angles (§ *a.*) ($B H F$ and $H F C$) on the same side of it, equal to two right angles; or the alternate angles (§ *b.*) ($E H B$, $A H F$, $H F C$, and $D F G$), equal to each other; or an exterior angle (§ 28.) ($E H B$) equal to its alternate and internal angle ($H F C$), these two straight lines are parallel.

PROPOSITION VII.

§ 31. The exterior angle (D B C) which is formed by producing any side (A B) of a triangle, is equal to the two interior and remote angles (A and D) of the triangle.

§ a. From B let B E be drawn parallel to A D ; also let A B be produced to C.

§ b. Because A D and B E are parallel (§ a.) and A C crosses them, the angles A and E B C (§ 28.) are equal to each other ; moreover D B, by crossing the same two parallels (D A and B E), makes (§ 29.) the alternate and interior angles (D and D B E) equal to each other ; the exterior angle D B C is made up of D B E and E B C, then substituting the whole for its parts (§ 24. § d.) we have (§ 24. § b.) the exterior angle D B C = A + D, the two interior and remote angles in the triangle A D B.

§ c. If either of the two other sides be produced, the proposition is proven in the same way.

PROPOSITION VIII.

§ 32. The sum of the angles of a triangle is 180° , or two right angles.

§ a. Produce a side (c) of any triangle to D. Then C B A and the exterior angle C B D (§ 25.) are equal to two right angles : and the exterior angle C B D, (§ 31.) is equal to the two remote angles C and A : therefore (§ 24. § b.) C, A,

and C B A are equal to two right angles : and C, A, and C B A are the three angles of the triangle (A C B) proposed.

§ b. *Cor.* If two angles of one triangle be known, the third is also known. It is found by subtracting the sum of the two known angles from 180° .

§ c. *Cor.* And the two acute angles of a right angled triangle (§ 17.) are together equal to one right angle.

§ d. Wherefore the acute angles of any right angled triangle are the complements (§ 8. § c.) of each other.

§ e. It is also evident from the above, that if two angles in one triangle be equal to two angles of another, the remaining angles are also equal to each other.

PROPOSITION IX.

§ 33. A diagonal (A C) of a parallelogram divides the parallelogram into two equal (§ 23.) triangles (A C D and A C B).

§ a. The opposite sides of a parallelogram (§ 19.) are parallel and equal to each other; wherefore $D C = A B$, $A D = C B$, and A C is common to the two triangles (A C D and A C B); therefore their sides are equal,

those of the one to those of the other. The angles D C A and C A B are equal to each other (§ 30.), for they are alternate angles (§ 28. § d.) made by A C crossing the two parallels D C and A B. For the same reason the alternate angles D A C and A C B made by A C with the parallels A D and C B, are equal to each other. Wherefore, the two angles (D C A and D A C) in one triangle being equal to two angles (A C B and C A B) in another, the remaining angles (D and B) (§ 32. § e.) are also equal to each other. Therefore, the triangle A C D having its sides and angles respectively equal to the sides and angles of the triangle A C B, is equal (§ 23.) to the latter, and the diagonal (A C) divides the parallelogram D A B C into these two equal triangles.

§ b. Scholium. The area (§ 10. § a.) of a parallelogram (§ 19. § b.) is the product of its base and altitude. The triangle A B C and the parallelogram D A B C have the same base (A B) and altitude (p), and the triangle is proven to be *half* of the parallelogram; Therefore,

§ c. Cor. The area or magnitude of a triangle is the product of its base by *half* its altitude.

§ d. Cor. The triangles into which a diagonal divides a parallelogram are both equal and (§ 23.) of the same magnitude.

§ e. Scholium. $D A C + B A C$ (§ a.) = $D C A + B C A$, and $D = B$. Therefore,

§ f. Cor. The opposite angles of a parallelogram are equal.

§ g. Cor. If the opposite angles of a quadrilateral figure be equal, figure is a parallelogram.

PROPOSITION X.

§ 34. If a parallelogram (D A C B) and a triangle (A B C) stand upon the same base (A C), and between the same parallels (D B and A C), they have the same altitude (p), and the triangle is equal to *half* the parallelogram.

§ a. If one side (A B) of the triangle be diagonal to the parallelogram, the triangle falls within the parallelogram, and (§ 33.) the proposition is proven.

§ b. But if the vertex (H) of the triangle proposed, fall without the parallelogram, as A H C, continue one of the parallels (D B) on, through the vertex H, to E; and upon the base A C construct the parallelogram A H E C, to which the side H C of this triangle is diagonal (§ 22. § a.), therefore A H C (§ 33.) is half of the parallelogram A H E C. The parallelograms A H E C and D A C B (§ 19. § a.) have the same base (A C) and altitude (p), and the area of each (§ 19. § b.) is the product of A C by p ; wherefore (§ 24. § b.) these two parallelograms are of the same magnitude; therefore (§ 24. § a.) the triangle A H C is also equal in *magnitude* to half of either parallelogram, say D B C A; and p (§ 18. § a.) is also the altitude of the triangle A H C.

§ c. *Cor.* If a triangle and a parallelogram have their bases and altitudes equal, the triangle is equal in magnitude to half the parallelogram.

§ d. *Cor.* Triangles which have the same or equal bases and altitudes, are of the same magnitude.

PROPOSITION XI.

§ 35. When two sides (A C and C B) of any triangle (A C B) are equal to two sides (E A and A C) of another (A E C), if the angles (A C B and C A E), which these sides contain, be equal, the two triangles are equal.

§ a. Let one of the equal sides (A C) be made common to the two triangles proposed, by constructing them on opposite sides of it; the figure A E C B, thus formed, will be a quadrilateral.

§ b. By the conditions of the proposition, the angle E A C = A C B, and they are alternate angles, made by A C with the equal lines E A and C B, therefore (§ 30.) E A and C B are parallel; and the opposite straight lines (E C and A B) which join their extremities are also parallel, wherefore (§ 30.) the alternate angles E C A and C A B are equal to each other.

§ c. E and B are the remaining angles of the two triangles, and (§ 32. § e.) they are equal to each other, for (§ b.) E A C + E C A = A C B + C A B, therefore the angles of the two triangles proposed are equal to each other.

§ d. Now, since E A C + B A C = E C A + B C A the whole (§ 24. § d.) E A B is equal to the whole E C B; and (§ c.) E = B; these four are the opposite angles of the quadrilateral A E C B, which therefore (§ 33. § g.) is a parallelogram, and (§ 19.) E C = A B, and (§ 33.) A C divides the parallelogram into the two equal triangles A C B and A E C.

§ e. *Cor.* If the opposite sides of a quadrilateral figure be either parallel or equal, the figure is a parallelogram.

PROPOSITION XII.

§ 36. Either side (b) of any triangle is less than the sum of the two other sides (a & c).

§ a . The straight line b , which joins the two points A and C, is less than the two straight lines c and a which join the same two points,

because the shortest distance between any two points (A and C) (§ 3.) is the straight line (b) which joins them; wherefore b is less than the sum of the two other sides of the triangle, or of any two lines that can join A and C.

PROPOSITION XIII.

§ 37. Any two triangles (C A B and D C A) are equal, if a side (A C), and the two angles (B A C and B C A) adjacent to it, in the one, be respectively equal to a side (C A) and the two angles (A C D and C A D) adjacent to this side in the other.

§ a . Let the equal side (A C) be made common, by constructing the two proposed triangles upon it, so that one of them may be on each side of the common line A C; the figure (B A D C) thus formed is a quadrilateral, and the side A C, which is common to the two proposed triangles, is a diagonal of it.

§ b . By the conditions of the proposition, the angles B A C and A C D are equal, and (§ 28. § d .) they are alternate angles, wherefore (§ 30. § d .) the two opposite sides (B A and C D) of the quadrilateral, are parallel. By supposition also, B C A and C A D are equal, and they are likewise alternate angles, wherefore (§ 30. § d .) the other two opposite sides (B C and A D) of the figure, are parallel.

§ c . If the opposite sides of a quadrilateral figure (§ 35. § e .) be parallel, the figure is a parallelogram; therefore B A D C is a parallelogram, and it is divided by the diagonal A C into the two proposed triangles C A B and D C A, which (§ 33.) are therefore equal to each other.

PROPOSITION XIV.

§ 38. Any triangles (B C A and D B C) are equal, if two angles (A & A B C) and an opposite side (C B), in one of the triangles

be respectively equal to two angles ($D \ \& \ B C D$) and the corresponding side ($B C$), of the other triangle.

§ a. Let the equal side ($B C$) be made common to the two triangles, by constructing them so that one will be on each side of $B C$.

Then $B C$ becomes diagonal to the quadrilateral figure $A C D B$, which is formed by thus constructing the two proposed triangles.

§ b. By supposition, $A = D$, and $A B C = B C D$; wherefore (§ 32. § e.) the remaining angles $A C B$ and $C B D$ are equal to each other, and they are alternate angles, therefore (§ 30. § d.) the two opposite sides, $C A$ and $D B$, of the four sided figure, are parallel; the other two opposite sides, $C D$ and $A B$, are also parallel, the alternate angles $A B C$ and $B C D$ being equal, by the conditions of the proposition. Therefore, the quadrilateral $A C D B$ (§ 35. § e.) is a parallelogram, and is divided by the diagonal $B C$; (§ 33.) into the two equal triangles $B C A$ and $D B C$.

§ c. Cor. Hence it is inferred, that if two angles and a side of one triangle be equal to two angles and a side of another, the two triangles are equal.

PROPOSITION XV.

§ 39. Any two triangles ($B A C$ and $B D C$) are equal, if every side of the former be equal to its corresponding side in the latter: e. g. $A B = D C$; $A C = B D$; and $B C = C B$.

§ a. Let one of the sides ($B C$) be made common to the two triangles proposed, by constructing one of them on each side of

$B C$; the figure ($A B D C$) thus formed is a quadrilateral, and the common side $B C$ is a diagonal of it.

§ b. By the conditions of the proposition $A B$ is equal to $D C$, and $A C$ to $B D$, and they are opposite sides of the quadrilateral figure $A B D C$; and if the opposite sides of a quadrilateral figure be equal (§ 35. § e.), the figure is a parallelogram; therefore $A B D C$ is a parallelogram, and its diagonal $B C$ divides it into the two proposed triangles $B A C$ and $B D C$, which (§ 32.) are therefore equal.

§ c. Scholium. Since the corresponding parts in equal figures (§ 23.) are equal, it follows:—

§ d. Cor. That, if the sides of one triangle be equal to the sides of another triangle, the angles opposite the equal sides are equal.

PROPOSITION XVI.

§ 40. Every equilateral triangle ($A B C$) is also equiangular.

§ a. Let an equilateral triangle (E D H) be drawn, having its sides equal to those of the proposed triangle. The two triangles (§ 39.) are then equal, and the angles A and D which correspond, (§ 39. § d.) are equal to each other.

§ b. By the conditions of the proposition each side of A B C is equal to the same thing, and by construction, equal to either side of E D H; then $AB = EH$; and the two triangles (§ a.) being equal the angles D and C, which are opposite to those equal sides (§ 39. § d.), are equal. Wherefore A and C are each equal to D, and, therefore, (§ 24. § a.) equal to each other. In the same manner B and A may be proven to be equal to each other. Wherefore C and B are each equal to A, and consequently the equilateral triangle A B C is equiangular.

§ c. Cor. Every equiangular triangle is also equilateral.

§ d. Scholium. Since the three angles of any triangle (§ 32.) are together equal to 180° , and the three angles of an equilateral or equiangular triangle, are equal to each other:

§ e. Cor. Every angle in any equilateral or equiangular triangle; contains 60° .

PROPOSITION XVII.

§ 41. The angles (A & C) at the base of an isosceles triangle A B C (§ 14.), are equal to each other.

§ a. Let the base (A C) of the proposed triangle, be divided into two equal parts (A D & D C) by a straight line (B D) drawn from the vertex (B) of the triangle.

§ b. This line (B D) divides the isosceles triangle into the two triangles A B D and D B C; in which every side of the one, is equal to the side which corresponds to it in the other; viz: $AB = CB$ (§ 14.) for they are the legs of the isosceles triangle A B C; $AD = DC$ (§ a.), by construction; and B D is common to both of the triangles; therefore (§ 39.) these two triangles (A B D and D B C) are equal, and the corresponding angles A and C, being opposite to the common side B D, are therefore (§ 39. § d.) equal to each other.

§ c. Scholium. $ABD = CBD$, because (§ 39. § d.) they are opposite to the two equal sides A D and D C; for a similar reason BDA and BDC are also equal to each other, and (§ 25.) these are together equal to two right angles, therefore each of them is a right angle, and the right line B D (§ 6. § b.) is perpendicular to the base (A C) of the isosceles triangle A B C; wherefore:—

§ d. Cor. A straight line drawn from the vertex, so as to bisect

the base of an isosceles triangle, is perpendicular to the base, and it divides the vertical angle ($A B C$) into two equal parts, and the isosceles into two equal triangles. Also;

§ *e. Cor.* A straight line ($B D$) that is drawn perpendicularly from the vertex, to the base of an isosceles triangle, bisects the vertical angle and the base.

PROPOSITION XVIII.

§ 42. If only two angles (A & B) of a triangle ($A C B$) be equal, the triangle is isosceles.

§ *a.* Call the other angle (C) (§ 16. § *b.*) the vertex of the proposed triangle; and from it, let the straight line $C D$ be drawn, so as to bisect the vertical angle (C) and divide the proposed triangle into the two $C A D$ and $C B D$, in which, by construction, the side $C D$ is common, the angles $A C D$ and $B C D$ equal, and (§ 42.) $A = B$; wherefore in these two triangles ($C A D$ & $C B D$), two angles and a side of the one are equal to the homologous angles and side of the other, and therefore (§ 38. § *c.*) these two triangles are equal to each other; consequently (§ 23.) the corresponding sides, $C A$ & $C B$, are equal, and hence, (§ 14.) the triangle $A C B$ is isosceles.

PROPOSITION XIX.

§ 43. In every right angled triangle ($A C B$), the square ($D A B E$) of the hypotenuse (§ 17. § *a.*) is equal in magnitude to the squares ($A C F H$ & $B C Q P$) of the two legs.

§ *a.* Let $D A B E$ represent the square (§ 20.) of the hypotenuse ($A B$), and $A C F H$ & $B C Q P$, the squares of the two legs $A C$ and $B C$; then (§ 43.) $D A B E = A C F H + B C Q P$.

§ *b.* From the right angle ($A C B$) let $C R$ be drawn parallel to the parallels (§ 20. & § 19.) $A D$ & $B E$, join $C D$ and $H B$.

§ *c.* The angles of a square (§ 20. § *a.*) are right angles, and all right angles (§ 6. § *a.*) are equal, therefore $H A C = D A B$; to each of these equals add the angle $B A C$, and the sums $H A B$ and $D A C$ (§ 24. § *b.*) will be equal; also $H A = A C$, because (§ 20.) they are sides of the same square $A F$; and $D A = A B$, because they also are sides of a square $A E$.

§ *d.* Wherefore, in the two triangles $A H B$ and $A D C$, the two sides $H A$ and $A B$ of the one,

are respectively equal to the two sides CA and AD , of the other, and the angles HAB and DAC , contained by these sides, are also equal (§ *c.*), therefore (§ 35.) the two triangles are equal.

§ *e.* The triangle ADC is equal in magnitude (§ 34.) to half of the parallelogram AR , for they stand upon the same base DA , and between the same parallels (§ *b.*) CR and AD . And the triangle AHB is equal in magnitude to half of the parallelogram AF , because they stand upon the same base AH , and between the same parallels HA and FCB .

§ *f.* The parallelograms AF and AR , being each double of either of the equal triangles (§ *d.*) AHB and ADC , are therefore (§ 24. § *b.*) equal to each other in magnitude; but the parallelogram AF (§ *a.*) is the square of the leg AC ; wherefore the square of the leg AC , and the parallelogram AR , are of the same magnitude.

§ *g.* By joining AP and CE , it may be demonstrated in the same manner, that the parallelogram BR , and the square (BPC) of the other leg BC , are of the same magnitude.

§ *h.* The parallelograms AR and BR make up the square ($DA BE$) of the hypotenuse (§ *a.*) AB , therefore (§ 24. § *a.*) the square of the hypotenuse (AB) is equal in magnitude to the sum of the squares of the two legs (AC & CB).

GEOMETRY.

PART II.

GEOMETRY.

DEFINITIONS.

§ 40. A circle is a figure that is bounded by a line of uniform curvature: all parts of this line are equidistant from a point (*a*) within it, which is called the *centre*.

§ a. If a straight line of any determinate length were to revolve in a plane, and on the point at one of its own extremities, its other extremity would describe the *circumference* (A D C H) of a circle; the point (*a*) on which the line would revolve would be the *centre* of the circle; the length of the revolving line would be the *radius* (*a B*) of the circle; and the plane in which the line would revolve, would be the *plane* of the circle.

§ b. The circumference (A D C H) of every circle is divided into 360 equal parts, called *degrees* ($^{\circ}$); every degree is divided into 60 equal parts, called *minutes* ($'$); every minute is divided into 60 equal parts, called *seconds* ($''$); and these, when calculations are performed in which great nicety is required, are divided into halves, tenths, or hundredths.

§ c. Whether the circumference of a circle be infinitely great, or infinitely small, a degree is still the same; and the circumference of the smallest is equal to the circumference of the largest circle, when the two circumferences are compared in degrees, minutes, and seconds, to each other; for a degree is the 360th part of the circumference of every circle.

§ d. Degrees ($^{\circ}$), minutes ($'$), and seconds ($''$), are the terms in which the value of angles is expressed.

§ *e*. When the straight lines which contain an angle, are produced to the circumference of any circle that may be described from the angular point as a centre, that part of the circumference which the two lines intercept, contains the degrees, etc., which express the value of said angle. An angle is said to *stand* upon the part of the circumference that is thus intercepted. Neither the length of the lines which contain the angle, or the distance of it from the circumference by which it is measured, affects its angular value.

§ 50. *The radius* of a circle is a straight line (*e*) that extends from the centre to the circumference of the circle.

§ *a*. All the radii of the same, or equal circles, are themselves equal.

§ 51. *The diameter* of a circle is a straight line (A C) that passes through the centre of the circle, and is terminated at each end by the circumference of the circle.

§ *a*. Either of the two parts (A B C & A H C) into which the diameter divides the circle, is a *semicircle*.

§ *b*. *A segment* of a circle is any part (*g*) cut from the circle by a line (*f*), or a plane, which crosses the circle.

§ 52. *An arc* of a circle is any part of its circumference. That part (A H) of 'the circumference which bounds a segment (*g*) is an arc; and the straight line (*f*) which joins the extremities of an arc, is a *chord*.

§ *a*. *The complement* of an arc, or angle, is the difference between either and 90° ; and the *supplement* is what either wants of being 180° .

§ *b*. The radius and centre of a segment, or of an arc, are the radius and centre of the circle, of which the segment, or the arc, is a part.

§ *c*. Every arc or angle has its sine and co-sine, tangent and co-tangent, secant and co-secant, besides its versed sine and semi-tangent.

§ *d*. The "co" is an abbreviation for *complement*: the co-sine, co-tangent, etc., of an angle or an arc, are the sine, tangent, etc., of the *complement* of that arc or angle.

§ *e*. The sine, tangent, secant, etc., of an arc, are also the sine, tangent, secant, etc., of the supplement of that arc.

§ 53. *A chord* is a straight line (*i*) (§ 52.) that joins the extremities of an arc (B C).

§ *a*. Every arc has its chord.

§ *b*. When a chord passes through the centre of a circle, it becomes a diameter, and the arc it subtends is a semicircle.

§ 54. *A sine* is a straight line (*o*) that extends from one extremity (B) of an arc (B C) perpendicularly to the radius (*a C*) that joins the other extremity.

§ 55. *A versed sine* is that part (*s C*) of the radius which is intercepted between the sine and the extremity of the arc.

§ 56. *A tangent* is a line (*b*) that touches one extremity of an arc (B C), is perpendicular to the radius (*a C*) at that extremity,

and extends to another radius (e) produced through (B) the other extremity of the arc.

§ 57. A *secant* ($a B e$) is the produced radius (e) that intersects the tangent.

§ *a.* The co-sine, co-tangent, and co-secant, of the arc BC , are p , $D t$, and $a t$; and p (§ 19.) is equal to $a s$.

§ *b.* The sine, co-sine, tangent, co-tangent, etc., of an angle, is the sine, co-sine; tangent, co-tangent, etc., of the arc which subtends that angle.

§ *c.* These are sometimes called *trigonometric functions*.

§ 58. A *sector* is a figure (h) contained by two radii ($a B$, $a C$), and the arc ($B O$) between them.

PROPOSITION I.

§ 59. An angle ($A B C$) at the circumference, is equal to half of an angle ($A H C$) at the centre, if they stand upon the same arc ($C A$), of a circle.

§ *a.* Draw the chord AC , and from B let a diameter ($B H D$) be drawn. The radii HA , HC , and HB (§ 50. § *a.*) are equal, and the triangles $A H B$ and $C H B$ (§ 14.) are isosceles. The exterior angle $C H D$ (§ 31.) is equal to the two interior angles ($H B C$ and $H C B$) of the triangle $C H B$; for the same reason the exterior angle ($A H D$) of the triangle $A H B$, is equal to its two interior angles $H A B$ and $H B A$, which are equal to each other, because (§ 41.) they are at the base of the isosceles

triangle $A H B$; therefore $A H D$ is double of either of them, say of $H B A$. For the same reason $H B C$ and $H C B$ are equal to each other, and $C H D$ is double of either, say of $H B C$.

The difference between $C H D$ and $A H D$, is $C H A$, and the difference between their equals, viz., twice $H B C$ and twice $H B A$, is twice $A B C$. Wherefore $C H A$ (§ 24. § *b.*) is equal to twice $A B C$; or, which is the same thing, the angle ($A B C$) at the circumference, is equal to half of the angle $A H C$ at the centre of a circle, and both of them stand upon the same base.

§ *b.* An angle at the centre of a circle, is measured (§ 49. § *e.*) by the arc it stands upon; Wherefore—

§ *c. Cor.* An angle at the circumference of a circle is measured by half the arc which subtends it.

§ *d. Cor.* All angles are equal that are at the centre, or all angles are equal that are at the circumference, if they stand upon the same, or equal arcs.

§ *e. Cor.* An angle that is at the circumference, and that stands upon a semicircle (§ *c.*), is a right angle.

PROPOSITION II.

§ 60. If the radius (A C) of a circle cut a chord (B H) at right angles, it bisects that chord and its arc (B C H).

§ a. Let the radii, A B and A H, be drawn to join to extremities of the chord (B H). The triangle (B A H) thus formed (§ 50. § a. & § 14.) is isosceles. And the straight line A F C bisects the vertical angle H A B (§ 41. § e.); for by the conditions of the proposition, A C is perpendicular to the chord B H, which is the base of the isosceles triangle B A H. Wherefore (§ 41. § d.) the two triangles B F A and H F A are equal, B H is bisected, and the angles B A C and

H A C are equal to each other, and being equal (§ 59. § d.) they stand upon equal arcs (B C & C H). Therefore the chord (B H), and its arc (B C H), are bisected by the radius A C.

§ b. Cor. If a radius bisect an arc, it also bisects the chord of that arc, and cuts the chord at right angles.

§ c. Cor. If a radius bisect a chord, it also bisects the arc of that chord, and cuts the chord perpendicularly.

§ d. Cor. If a radius bisect a chord, or its arc, it also bisects the angle at the centre, which stands upon that arc.

PROPOSITION III.

§ 61. B C, half the chord (B D) of an arc (B E D), is the sine of C A B, half the angle (D A B) which that arc subtends.

§ a. Let the chord be bisected at C, and through C let the radius A C E be drawn, then this radius (§ 60. § c.) bisects the arc B E D, cuts the chord B D at right angles, and also (§ 60. § d.) bisects the angle (D A B) which this arc subtends. Wherefore, B A C is half of the angle D A B, B C is half the chord of B E D, and it is perpendicular to the radius A C E; therefore (§ 54.) B C, half the chord of B E D, is the sine of C A B, which is half of the angle (D A B) proposed.

PROPOSITION IV.

§ 62. In any circle, radius (A D), the sine (A H) of 90° , the

chord (BD) of 60° , and the tangent (DC) of 45° , are all equal to each other.

§ a. Let A be the centre of the circle, the arc H B E D = 90° , the arc B E D = 60° , and the arc E D = 45° , and join B A and C A. The angles at the centre (A) (§ 49. § c.) are measured by the arcs they stand upon; therefore the angle D A C = 45° , D A B = 60° , and D A H = 90° ; A H then (§ 6. § b.) is perpendicular to A D, and A H (§ 54.) is the sine of the arc H B E D = 90° , it is a radius, and therefore (§ 50. § a.) equal to A D.

§ b. The radii A B and A D being equal (§ 50. § a.), makes the triangle B A D (§ 14.) isosceles; consequently (§ 41.) the angles A B D and A D B are equal. The angle D A B = 60° (§ 49. § c.) because it stands upon the arc B E D; wherefore (§ 32.) A B D + A D B = 120° , and being equal, the value of each is 60° ; therefore the triangle B A D is equiangular, and (§ 40. § c.) also equilateral; consequently (§ 13.) the chord (B D) of 60° is equal to radius (A D).

§ c. C D is the tangent of E D = 45° , and consequently (§ 56.) is perpendicular to A D; wherefore (§ 6. § b. & § a.) the angle C D A = 90° , and (§ 17.) the triangle A D C is right angled. The angle C A D = 45° (§ 49. § c.), because it stands upon the arc E D, therefore (§ 32. § d.) the angle A C D is also equal to 45° , and is equal to C A D, and (§ 42.) the triangle A D C is isosceles, and (§ 14.) the tangent (D C.) of 45° is equal to radius (A D).

§ d. Therefore the tangent of 45° (§ c.), the chord of 60° (§ b.), and the sine of 90° (§ a) being each equal to radius, are (§ 24. § a.) equal to each other.

PROPOSITION V.

§ 63. In every triangle, the angle (A) that is opposite to the greatest side (a) is the largest, and (B), that which is opposite to the smallest side (b), is the smallest angle of the triangle.

§ a. Describe a circle (A C H B) about the proposed triangles B A C, the circumference of which touches the three angular points (B, A, & C) of the triangle. Each side of the triangle then becomes the chord to the arc, which subtends the angle that is opposite to it.

§ b. The angle A stands upon the arc B H C, which is greater than either of the arcs (B A, A C) upon which the

two other angles (C & B) of the triangle stand. Each of these three angles (§ 59. § c.) is measured by half the arc that subtends it. Therefore A, which stands upon the greatest arc, and subtends the greatest side (a), is the largest angle of the proposed triangle.

§ c. Half the smallest arc (A C) (§ 59. § c.) measures the angle (B) that stands upon it; therefore B (the angle that is opposite to the smallest side) (b) is the smallest angle of the triangle.

DEFINITIONS.

§ 64. The *multiple* of a magnitude is the product of this magnitude and any other factor.

§ a. *Equimultiples* of magnitudes are the product of each of these magnitudes by the same or equal multipliers.

§ b. Thus, 15 and 30 are equimultiples of 3 and 6; for $3 \times 5 = 15$, and $6 \times 5 = 30$. Consequently (§ 24. § b.)—

§ 65. The same or equal multiples of equal magnitudes are equal to each other.

§ 66. *Ratio* is the relation which the value of any magnitude bears to that of another, and it is shown by dividing one magnitude by the other.

§ a. Thus, the ratio of a to b is $a \div b$, and is expressed thus,— $a : b$.

§ b. And if the ratio between two quantities (a & b) be equal to the ratio between two other quantities (c & d), this equality of ratio is expressed (§ XLV. Algebra) by writing the sign ($::$) between the two former and the two latter quantities, thus,— $a : b :: c : d$.

§ 67. *Proportion* consists in the equality of the ratios between magnitudes.

§ a. Thus, the ratio (§ 66.) of 3 to 4 is $\frac{3}{4}$; and the ratio of 6 to 8 is $\frac{6}{8} = \frac{3}{4}$; and these quantities are proportional; *i. e.* $3 : 4 :: 6 : 8$.

§ b. Four quantities are in *direct* proportion, when the 4th is equal to the quotient, which arises from dividing by the 1st quantity, the product of the 2d and 3d. Thus ($3 : 4 :: 6 : 8$), $4 \times 6 = 24$, and $24 \div 3 = 8$. So, also, $a : b :: c : d$, which in Algebra (§ XLV.) is but another form for expressing that $a \div b = c \div d$; and by transposition $a \times d = c \times b$; also, $(c \times b) \div a = d$.

§ c. The first and third (a & c) of four magnitudes that are in *direct* proportion, are called *antecedents*; and the second and fourth (b & d) are called *consequents*.

§ d. Also the first and fourth (a & d) are called *extremes*; and the second and third (b & c) are called *means*.

§ e. It is a rule in proportion, that the quantities for calculation be so arranged that the product of the two extremes be equal to the product of the two means. Thus, $a \times d = b \times c$; and as $a \times d = d \times a$. (§ XXV. †1. Algebra), $d \times a = c \times b$. Wherefore the means may be made extremes, and the extremes means; as, $b : a :: d : c$ (§ XLVIII. Alg.); the antecedents may be made consequents and the consequents antecedents; as, $d : c :: b : a$, without interrupting the harmony of the proportion between the quantities.

§ *f*. Hence if the value of three magnitudes be known, the unknown value of the fourth, which is in the same ratio of proportion, is determinable. It is the quotient that arises (§ *b*.) from dividing the product of the two means by the known extreme. Thus, $3 : 4 :: 6 -$; a 4th quantity, $4 \times 6 = 24$, and $24 \div 3 = 8$, the 4th quantity. Generally speaking, the magnitude whose value is required is expressed last in the order of proportion.

AXIOMS.

§ 69. Among quantities that are proportional, equals may be substituted for equals.

§ *a*. Magnitudes that are proportional to the same two, or to other magnitudes equal to these, are proportional to each other.

§ *b*. Equal magnitudes have the same ratio to the same magnitudes.

PROPOSITION VI.

§ 70. The same, or equimultiples (C and D), of any two magnitudes (A and B), are to each other as the magnitudes themselves.

§ *a*. Let C be the same multiple, say the 5th, of A, that D is of B; then (§ 64. § *a*.) $A \times 5 = C$, and $B \times 5 = D$; by transposition $C \div A = 5$, and $D \div B = 5$; wherefore (§ 24. § *a*.) $C \div A = D \div B$; then (§ XLVI.) $C : A :: D : B$, and alternately (§ XLVIII.) $C : D :: A : B$. Therefore, the equal multiples are as the magnitudes.

§ *b*. Scholium. The magnitude of a triangle (§ 33. § *c*.) is the product of its base and half of its altitude.

§ *c*. Wherefore the magnitudes of triangles of the same altitude, are equimultiples of their bases. And so of parallelograms of equal altitudes; and therefore,

§ *d*. Cor. Triangles, or parallelograms, that have the same altitude, are, in magnitude to each other as their bases; or those that have equal bases are to each other as their altitudes.

PROPOSITION VII.

§ 71. When the product of any two quantities (*a* & *b*) equals the product of two others (*c* & *d*), the ratio of the greater multiplicand to the greater multiplier, is equal the ratio of the less multiplicand to the less multiplier; and the four quantities are proportional.

§ *a*. Let $a \times b = c \times d$ be the four quantities proposed, and let *a* be the greater multiplicand, then *d* will be the greater multiplier, *b* the less, and *c* the less multiplicand; and (§ 71.) $a : d :: c : b$.

§ *b*. By the conditions of the proposition $a \times b = c \times d$, and by transposition (§ XLII.) $a \div d = c \div b$; therefore these quantities (§ XLV.) are proportional; i. e., $a : d :: c : b$, and consequently (§ 67. § *a*.) their ratios are the same.

PROPOSITION VIII.

§ 72. If a straight line (D E) be drawn parallel to the base (C B) (§ 16. § b.), and so as to cut the two sides (A C and A B) of any triangle (A B C), the sections (A D, D C, A E, & E B) of these two sides will be proportional; *i. e.*, $A D : D C :: A E : E B$.

§ a. Join D B and C E; and let E F be drawn from the vertex (E) of the two triangles A E D and C E D, perpendicularly upon A C, then (§ 18. § a.) E F is the altitude of each of these two triangles. In the same manner, by drawing D H perpendicular to A B, it is shown that the two triangles A D E and B D E have the same altitude (D H).

§ b. The triangles A E D and C E D, having the same altitude (E F), are to each other (§ 70. § d.) as their bases; *i. e.*, $A E D : C E D :: A D : D C$. And the triangles A D E and B D E are to each other also as their bases; *i. e.*, $A D E : B D E :: A E : E B$.

§ c. The triangle A D E is a magnitude in each set of these proportions; and the triangles C E D and B D E are of the same magnitude (§ 34. § d.), for they stand upon the same base (D E), and between the same parallels (§ 72.) D E and C B.

§ d. Wherefore A D and D C, A E and E B, are proportional to the same or equal magnitudes; they are therefore (§ 69. § a.) proportional to each other; *i. e.*, $A D : D C :: A E : E B$.

§ e. By drawing a straight line from the vertex B, perpendicularly upon A C, as a base; and another from C as a vertex, perpendicularly upon A B, it may be proven in the same way, that $A C : D C :: A B : E B$. And also that $A C : A D :: A B : A E$. Wherefore,—

§ f. *Cor.* If the two sides of a triangle be crossed by a line that is parallel to the base, these two sides will be proportional to their sections.

PROPOSITION IX.

§ 73. The homologous (§ 23. § c.) sides of similar triangles (A B C & D E F) are proportional to each other, *viz.*, $A B : c :: A C : b :: C B : a$.

§ a. By the conditions of the proposition, the triangles A B C and D E F are similar, wherefore (§ 23. § b.) their corresponding angles are equal, *viz.*, $B = E$, $A = D$, and $C = F$. Upon the two sides A B and A C of the greater triangle, (A B C) let A G be set off, equal to c, and A H = b; let G H be joined, then (§ 35.) the two triangles A G H and D E F are equal to each other; therefore (§ 23.) $G H = a$, the angle A G H = E, etc.

§ b. The angle A G H (§ a.) = E, and B = E, therefore (§ 42, § a.) A G H = B, and (§ 30. § d.) G H is parallel to B C. Consequently (§ 72. § f.) $AB : AG :: AC : AH$; by construction $AG = c$,

and $AH = b$; then substituting for AG and AH their equals, we have (§ 69.) the proportion $AB : c :: AC : b$.

§ c. Then by drawing from G, GP parallel to AC, the parallelogram G P C H (§ 35. § e.) is formed; and (§ 72. § f.) we have $AB : AG :: CB : CP$. But (§ 19.) $CP = GH$, and (§ a.) $GH = a$; also $AG = c$. Therefore (§ 69.) $AB : c :: CB : a$.

§ d. Cor. Whence it may be inferred, that if a straight line be within a triangle and parallel to its base, the ratio of the base to this line will be equal to the ratio of the sides to their sections.

PROPOSITION X.

§ 74. In every triangle (ABC) the sides are proportional to the sines of their opposite angles.

§ a. From C and A, as centres, and with AC as the radius, let the arcs AD and CE be described, and draw AF perpendicular upon BC, and CH perpendicular upon AB, then (§ 54.) AF is the sine of the angle ACB, and CH is the sine of the angle CAB.

§ b. Of the two triangles BHC and BAF, the angle at B is common, the right angles AFB and CHB are equal, wherefore (§ 32. § e.) the remaining angles HCB and FAB are equal, and (§ 23. § b.) these two triangles are similar.

§ c. The homologous sides of similar triangles (§ 73.) are proportional; wherefore $AB : CB :: AF : CH$; and AF & CH (§ a.) are the sines of the angles ACB and CAB; therefore $AB : CB :: \text{sine } ACB : \text{sine } CAB$. In the same manner it may be proven that $AC : CB :: \text{sine } ABC : \text{sine } CAB$.

§ d. If the proposed triangle be right angled, and the hypotenuse be made radius, the hypotenuse becomes (§ 62. § a.) the sine of the right angle, and the legs (c and a) the sines of their opposite angles (C & A), whence we have a self-evident truth, viz., $AB : CB :: c : a$; but c and a are the sines of C and A, therefore $AB : CB :: \text{sine } C : \text{sine } A$. Also $AC : AB :: b : c$;

G

but b is the sine of B , and c of C , therefore $AC : AB :: \text{sine } B : \text{sine } C$; and (§ 62.) the sine of B is equal to radius. By like reasoning, it is shown that $AC : CB :: \text{sine } B : \text{sine } A$. Wherefore,

§ *e. Cor.* If an hypotenuse be made radius, that hypotenuse is to either leg as radius is to the sine of the angle opposite that leg.

PROPOSITION XI.

§ 75. In every right angled triangle, the sides are proportional to the several *trigonometric functions* (§ 57. § *c.*) of the two acute angles.

§ *a.* Let the hypotenuse (b) of the proposed triangle, be made radius (AC) to an arc $CD = A$. Then (§ 54. & § 57. § *a.*) CB is the sine, and AB the co-sine of A ; likewise AB is the sine, and CB the co-sine of C .

§ *b.* Now (§ XXV. †1.) $b \times a = CB \times AC$; then (§ 71.) $b : AC :: CB : a$; by construction (§ *a.*) AC is radius, and CB is sine A or co-sine C ; therefore $b : \text{radius} :: \text{sine } A \text{ or co-sine } C : a$. Again, $b \times c = AB \times AC$, and AB (§ *a.*) is the co-sine of A , and sine of C ; therefore, $b : \text{radius} :: \text{co-sine } A \text{ or sine } C : c$. And these quantities (§ XLVII.) are also proportional, when taken inversely or alternately.

§ *c.* Let either of the legs (c) be made radius (AB) to another arc $EB = A$. Then CB becomes tangent (§ 56.) to A , and (§ 57. § *b.*) co-tangent to C ; and AC (§ 57.) the sec. of A , and co-sec. of C . And (§ XXV. †1.),

1st. $AB \times a = CB \times c$, and (§ 71.) $AB : c :: CB : a$.

2d. $AB \times b = AC \times c$, „ $AB : c :: AC : b$.

3d. $AC \times a = CB \times b$, „ $AC : b :: CB : a$.

Now (§ *c.*) AB is radius, CB is tangent A , or co-tangent C , and AC is sec. A , or co-sec. C . Therefore in these three sets of proportions, the first is, radius : $c :: \text{tangent } A$, or co-tangent $C : a$. The second is, radius : $c :: \text{sec. } A$, or co-sec. $C : b$. And the third is, sec. A , or co-sec. $C : b :: \text{tangent } A$, or co-tangent $C : a$. And (§ XLVIII.) these quantities are also proportional, when taken inversely, or alternately.

§ *d.* If BC be made radius, the same method of demonstration will show that radius, the tangent and secant of C , and of its complement, are proportional to the sides (a , b & c) of the proposed triangle.

PROPOSITION XII.

§ 76. The chords (a & b), sines (dp & es), tangents ($e s$ & BC), etc., of equal arcs (ds & eB), which have different radii (AB , As), are to each other, as the radius of one of the arcs is to the radius of the other.

§ a. The proposed arcs (*ds* & *eB*) are concentric; *es* is the tangent of *ds*, and *CB* of *eB*; by the definition of a tangent (§ 56.), they are perpendicular to *AB*; they are therefore parallel; and (§ 73. § d.) $se : BC :: \text{radius } As : \text{radius } AB$.

§ b. The sines (*dp* & *es*) of these two arcs, are also parallel, and by the same proposition (§ 73. § d.) $dp : es :: As : AB$.

§ c. The chords *a* and *b*, are also parallel, and, for the reason above, are to each other as, $As : AB$.

§ d. By similar methods of demonstration the secants, co-secants, co-sines, co-tangents, etc., of the two arcs, may be proven to have the same proportion to each other, which the two radii *As* and *AB* have.

PROPOSITION XIII.

§ 77. The sum (*BC*) of two sides (*CA* & *AH*) of any triangle (*ACH*), is to the tangent of half the sum of their adjacent angles (*H* & *C*), as the difference (*Cp*) between the same two sides, is to the tangent of half the difference between the same two angles; or $BC : \text{tangent } \frac{1}{2} (ACH + AHC) :: Cp : \text{tangent } \frac{1}{2} (ACH - AHC)$.

§ a. With the greatest side (*AH*) of the proposed triangle, as radius, describe the circle *BHp*, about the centre *A*. The side *AC* is extended both ways, until it forms the diameter (*Bp*) of the circle. Join *BH*, *Hp*. *DC* is drawn parallel to *HP*.

§ b. Because $AH = AB$ (§ 50. § a.); *CA* + *AB*, or *CB* is the sum of the two sides *CA* & *AH*. And because $AH = Ap$; $Ap - AC$, or *Cp* is the difference between the same two sides.

§ c. The angle *BHp* (§ 59. § e.) is a right angle; then *CD* is perpendicular to *BH*, for it is drawn parallel to *HP*; therefore (§ 30.) *CDB* is a right angle; and *BD* is tang. of *BCD*.

§ d. The exterior angle *HAB* (§ 31.) is equal to the sum of the adjacent angles (*ACH* & *AHC*); *HpB* (§ 59.) is equal to half of *HAB*, for they stand upon the same arc (*BH*); then (§ 24. § a.)

$HpB = \frac{ACH + AHC}{2}$. Because *DC* and *Hp* (§ a.) are parallel, *BCD* (§ 28.) is equal to *HpB*; therefore *BCD* is equal to

half the sum of the two angles $A C H$ and $A H C$. And in the right angled triangle $B D C$, $C B$ is the sum (§ *b.*) of the two sides $A H$, $A C$ of the proposed triangle $A C H$, and $B D$ (§ *c.*) is the tangent of $B C D$, which is half the sum of $A C H$ and $A H C$.

§ *e.* By § 31, the angle $A C H = C p H + C H p$. Because $A H = A p$ (§ 50. § *a.*), the triangle $H A p$ (§ 14.) is isosceles; and (§ 41.) $C p H = A H p$. Then (§ 24. § *a.*) $A C H = A H p + C H p$; from this sum, subtracting $A H C$, the remainder is twice $C H p$, which is the difference between the two angles $A C H$ and $A H C$; then $C H p$ is *half* this difference. And (§ 29.) $C H p = H C D$; therefore $H C D$ is half the difference between the angles $A C H$ and $A H C$. Now making $C D$ radius, $D H$ (§ 56.) becomes tangent of $H C D$.

§ *f.* Now $C p$ being the difference (§ *b.*) between the two sides $A H$ and $A C$; and $D C$ being parallel (§ *a.*) to the side $H p$ of the triangle $H B p$; we have (§ 72.) $B C : B D :: C p : D H$. Or,
 $C A + A H : \text{tangent } \frac{A H C + A C H}{2} :: C A \propto A H : \text{tangent } \frac{A H C \propto A C H}{2}$

§ *g.* Scholium. The half sum (§ *d.*) $B C D$ added to the half difference $H C D$ (§ *e.*) makes the greater angle $A C H$; and the half difference $C H p$ (§ *e.*) subtracted from the half sum $A H p$ (§ *e.*), gives the less angle $A H C$. Wherefore,

§ *h.* *Cor.* Half the difference and half the sum of any two magnitudes being added to each other, give the greater, and being subtracted from each other, give the less of the two magnitudes.

PROPOSITION XIV.

§ 79. The base (e) of any triangle ($A B C$) is to the difference between the two sides (b & c), as their sum is to twice the distance from the middle of the base to a perpendicular ($A a$) falling upon the base from its opposite angle (A); that is, $e : b \propto c :: b + c$ is to twice the distance of a from the middle of the base.

§ *a.* With a radius equal to the longer side (b) of the proposed triangle, the circle $E C R H$ is described about the angle (A) that is opposite to the base. Then b (§ 50. § *a.*) is equal both to $A E$ and to $A R$; and the difference between the two sides b and c is ($A R - c =$) $B R$; and their sum is ($c + A E =$) $B E$;

§ b. Because the perpendicular Aa is drawn from the centre of the circle upon the chord CH (§ 60.), it bisects it. Then the distance of the perpendicular at a from the middle of the base (e), *plus*, half the base, makes up (Ca) half the chord CH . Double this, and we have the whole chord CH , which is made up of twice the distance from a to the middle of the base, and twice the half of the base e . Twice the

half, is equal to the whole base e . Therefore subtracting the base e from the chord CH , the remainder (BH) is twice the distance of the perpendicular at a from the middle of the base.

§ c. The two sides CB, BE of the triangle $EB C$, are the base (e), and the sum of the two sides ($b \& c$) of the proposed triangle. And the two sides BR, BH of the triangle HBR , are the difference between those sides ($b \& c$), and twice the distance (§ b.) from the perpendicular to the middle of the base (e). These two triangles ($EB C \& HBR$) (§ 23. § b.) are similar; for the vertical angles $EB C \& HBR$ (§ 27.) are equal; and $HCE = HRE$ (§ 59. § d.), they stand upon the same arc (HE); and the remaining angles $CE R, CHR$, (§ 32. § e.) are equal. Therefore (§ 73.) the homologous sides of these two similar triangles are proportional; that is, $CB : BR :: BE : BH$; or, $e : b \& c :: b + c : \text{twice the distance of the perpendicular at } a \text{ from the middle of the base.}$

§ d. Scholium. Then if the distance of the perpendicular from the middle of the base be added to *half* the base, the sum will be the greater segment (Ca); or, if it be subtracted, the difference will be the smaller segment (Ba) (§ 77. § h.).

§ e. The distance of each angle from the perpendicular are the segments of the base.

LOGARITHMS.

LOGARITHMS.

§ 80. The purpose of logarithms is to facilitate arithmetical calculations. The term is derived from two Greek words (*logos* and *arithmos*), and may rightly be called the language of numbers; for by means of logarithms, not only multiplication and division, but also the tedious operations of involving powers, extracting roots, etc., are simplified. They are performed by the simple process of addition and subtraction, multiplication and division.

§ a. Through the intervention of logarithms, angular and linear magnitudes are compared with each other, as quantities of the same denomination are in common arithmetic; and the unknown value of a line, arc, or an angle, may be deduced from the known ratio between other lines and angles.

§ b. Before the invention of Lord Napier had introduced into mathematical calculations the use of logarithms, the solution of trigonometrical problems was referred to synthesis, and obtained by construction. The process of finding the value of unknown quantities in trigonometry was tedious; and the result, owing to the mechanical manner in which the operation was conducted, was subject to partial inaccuracies.

§ c. If the logarithms that correspond to a series of numbers in geometrical progression, be taken out and noted down, they will be found to constitute another series of numbers in arithmetical progression. And if two series of numbers be arranged, one in the order of geometrical progression (the first term of which shall be unity or 1, and the common ratio 10), and the other in the order of arithmetical progression, (the first term of which shall be zero (0), and the common difference 1), these two series will constitute a basis, or the ground work for forming a table of logarithmic numbers, like those most generally used.

§ d. By arranging the two series of numbers, the one in geometrical, the other in arithmetical order of progression, thus,

Geometrical progression.	-	-	-	-	-	Arithmetical progression.*
1	-	-	-	-	-	0
10	-	-	-	-	-	1

10000000000	-	-	-	-	-	10,

H

the relation and connexion between the orders of the two series will appear. The terms in the order of arithmetical progression, are the logarithms of those in the geometrical order: each the logarithm of the term to which it is opposite; i. e., 0 is the logarithm of 1; the logarithm of 10 is 1, of 100 is 2, of 1000 is 3, of 10,000 is 4, and of 100,000 it is 5, etc.

§ e. By observing the different relations which exist between the terms in the two series above, it appears,—

1st. That the logarithm of any whole number has for its index the figure, which expresses the number of digits, *minus one*, that are in the natural number for which the logarithm is required. Thus 1 is the logarithmic index of 10, which has two digits; 2 is the logarithmic index of 100, which has 3 digits; 3 of 1000; 4 of 10,000, etc.

2d. That the logarithm of any number intervening between 1 and 10, must be a fraction less than unity; for the logarithm of 1 is 0, and of 10 it is 1; then the logarithm of any number between 1 and 10 must be less than 1. The logarithm that corresponds to any number between 10 and 100, must be greater than 1 and less than 2, etc.

3d. That the product of any two numbers in the series of geometrical progression, answers to the sum of the two numbers in the arithmetical order, which correspond to them. Thus; 100,000,000 in the geometrical, answers to 8 in the arithmetical order, and 100,000,000 is the product of $1000 \times 100,000$, which two numbers correspond with 3 and 5 in the arithmetical series; and in this series $3 + 5$, or $8 = 100,000,000$ in the geometrical series. Now 3 is the logarithm of 1000, and 5 of 100,000. Hence, therefore, if the logarithms of any quantities whose product is required, be added together, this sum will be the logarithm of the required product.

4th. That the difference (4) between any two numbers (2—6) in the series of the arithmetical order of progression, is the logarithm of the quotient (10,000) which arises from dividing by each other, the two numbers ($1,000,000 \div 100$) that correspond, in the geometrical order, to the two said arithmetical terms (2 and 6). And,

5th. That logarithms of numbers are a series of terms in the order of arithmetical progression, which series corresponds to another series of numbers in the order of geometrical progression.

§ f. The logarithm of 10 is not necessarily 1. Any other number as well as 1 may be assumed as the logarithm of 10. But if any other number were taken as the logarithm of 10, it would establish another base for calculating a table of logarithms, and this change would effect the logarithm of every other number in the same ratio. From this it appears that the value of a logarithm is entirely conventional. But in order to simplify, and facilitate their application to practice, mathematicians have assumed, in the order of geometrical progression, a series of numbers in the ratio of 1, 10, 100, 1000, 10,000, etc.; and as logarithms to these, they have assigned, in arithmetical progression, a series of numbers in the

order of 0, 1, 2, 3, 4, etc., having 1 for the common difference. The latter numbers, taken in the order in which they stand, are called the logarithmic *indices*, or *characteristics*, of the former, taken in the same order. Whence (§ e. 1st) the logarithmic index of every whole number, is made always to express *one less* than the number of digits contained in the whole number. Thus, the characteristic of 100 is 2, as the number of digits or figures in 100, is 3. The number of digits in 1000 is 4, and the logarithmic characteristic of 1000, is 3.

§ g. The logarithmic signs and tangents, co-sines and co-tangents, etc. of degrees, minutes, and seconds, are also of conventional value. They are expressed in parts of the radius of a circle; the value of which radius is assumed to be equal to 10,000,000, etc., with as many ciphers affixed as the compiler intends the *mantissa* shall consist of digits.

§ h. The *mantissa* is the decimal part of a logarithm; or the part which is not the index. The logarithm of 250 is 2 .397940; 2 is the index, and .397940 is the mantissa.

§ 81. The characteristic of a logarithm depends upon the number of digits which are contained in its *geometrical** number; being one less than the number of digits, it is known by counting the figures of the geometrical number, and writing down one less than their number for the index.

§ 82. The mantissæ have been previously calculated and arranged in a tabular form, and in such a manner that the mantissa for any geometric number, (however great or small), may be determined with readiness.

§ 83. The first column of the tables (I.) is marked N. (Numbers.) It contains the geometrical numbers, from 1 to 999. The mantissa of each term in this series, is in a line with its geometrical number, and in the next column which is marked 0. The nine other columns, headed with the cardinal numbers 1, 2, 3, etc., to 9, also contain mantissæ; but these are of geometrical numbers that have *four* digits; the last figure of which, being found at the head of one of these columns, and the three first in the first column (N), show at their angle of meeting, the proper mantissa. Thus, the logarithm of 3681 is 3.565966; 368 being found in the first column, N., the mantissa for 3681 is found in a line with 368, and in the column, at the top and bottom of which, stands 1.

§ 84. To take from the table (I.) the mantissa for any geometrical number less than 1000.

§ a. Find the given number in the first column (N.); its mantissa is opposite to it in the next column (0).

§ b. The mantissa for 9 is .954243; for 14 it is .146128; and for 964 it is .984077.

* The natural numbers, which correspond to, or are represented by, a logarithm, are here called *geometrical* numbers, from their being terms in the geometrical series¹ of progression. Thus 419, of which 2.622214 is the logarithm, is the *geometrical* number of log. 2.622214.

§ c. These mantissæ, with the proper characteristics prefixed, constitute the logarithms of those numbers; thus, logarithm of 9 = 0.954243; of 14 = 1.146128; and of 964 = 2.984077.

§ 85. To take from the tables, the mantissa for any geometrical number that is greater than 1000, but less than 10,000.

§ a. Find, in the first column (N.) of the tables, the three first figures of the proposed number; in a line with them, and in the column over which the fourth figure stands, is the proper mantissa.

§ b. The mantissa (.973590) for 9410 is found in the column marked (0), and opposite to 941 in the first column; and the mantissa (.954918) for 9014, is found in the column marked (4), and opposite to 901 in the first column (N.).

§ c. The geometrical numbers in this case have four digits; 3, then, is the characteristic of their logarithms; which are, 3.973590 = 9410; and 3.954918 = 9014.

§ 86. To take from the tables the mantissa of any geometrical number that has more than *four digits*, or that is greater than 10,000; say of 43568.

§ a. Take out the mantissa for the four first digits (§ 85. § b.), and subtract it from the mantissa next in order. Then say,—If unity (1), prefixed to as many ciphers as there are digits remaining of the proposed geometrical number, give this mantissal difference, what mantissal difference will the remaining digits of the geometrical number, give? This last mantissal difference being added to the mantissa for the four first digits, produces the required mantissa.

§ b. The mantissa for the four first digits (4356) of 43568 is .639088; the mantissal difference between this and the next (.639188) in order, is .000100; one digit (8) of the proposed geometrical number remains; and unity (1) (§ a.) must be prefixed to one cipher (0), which makes (10); then the order and terms of the proportion are, 10 : .000100 :: 8 : .000080. This last term, *plus* the former mantissa, (or .639088 + .000080) = .639168, the mantissa required.

§ c. The geometrical number (43568) in this example has *five* digits; then (4) being prefixed as an index to the mantissa (.639168) makes the logarithm of 43568 = 4.639168.

§ d. The mantissa for the four first digits (7419) of 741946 is .870345; the difference between the mantissa of 7419, and of 7420, is .000059. And the order and terms of the proportion are, 100 : 000059 :: 46 : .000027. This last term being added, and the characteristic (5) being prefixed to the mantissa (.870345), makes the logarithm of 741946 = 5.870372.

§ e. The mantissa for the four first digits (5941) of 594106734 is .773860; the mantissal difference = .000073; the remaining digits (06734) are *five* in number. Prefixing 1 to *five* ciphers, the proportion is 10000 : 000073 :: 06734 : 000004. Prefixing the characteristic (8) to .773860 + 000004, makes the logarithm of 594106734 = 8.773864.

§ f. The mantissa for 124, and the mantissa for 1240000000 are

the same (.093422). But the logarithm of $124 = 2.093422$; and the logarithm of $1240000000 = 9.093422$. Hence,

§ g. The effect of final ciphers in a geometrical number, on its logarithm, is confined to the characteristic of the logarithm, for the logs. (§ f.) of 124 and 1240000000 have the same mantissa.

§ 87. To find the logarithm of a geometrical number that is mixed with a decimal fraction.

§ a. The mantissa is found as it would be, were the proposed number integral; but the characteristic of the logarithm must express one less than the number of digits in the *integral* part of the number proposed. Thus;

Mixed Geometrical Nos.	Their Logarithms.
9414.5 - - -	= 3.973797
941.45 - - -	= 2.973797
94.145 - - -	= 1.973797
9.4145 - - -	= 0.973797

§ 88. As the logarithm of unity, or (1), is 0, it follows that the logarithm of any quantity less than unity, or the logarithm of a fraction, must be less than 0; that is, it is a *negative quantity*. Thus,—

Logarithm of 1 =	0	.000000
Logarithm of 0.1 =	-1	+.000000
Logarithm of 80 =	1	.903090
Logarithm of 0.08 =	-2	+.903090

§ a. But the use of negative and positive quantities (such as the logarithms of integers and of fractions, as just quoted above), in the same operation, has a tendency sometimes to perplex the calculator. It is better, therefore, that all quantities in the same sum should be affected with like signs. This may be effected with the logarithms of fractions by means of a little artifice, by which negative quantities are made to change their signs, or become as positive quantities.

§ b. This artifice consists in borrowing and applying 10, or 20, or 100, etc., to the logarithmic index of the fraction, and restoring the borrowed quantity again during the progress of the calculation. Thus, in the summing up of the logarithms of 80, and of 0.08, instead of adding the mantissæ and subtracting the characteristics of the two logarithms ($1.903090 - 2 + .903090 = 0.806180$), the operation may be performed entirely by addition, if the arithmetical complement of -2 , which is 8, be used as the index; thus, $1.903090 + 8 + .903090 = 10.806180$; rejecting the 10, which was borrowed in the logarithmic index of 0.08, there remains 0.806180.

§ c. Any quantity with the sign (—) prefixed, may be commuted into a positive quantity by substituting for that quantity its *arithmetical* complement. In this way subtraction may be performed by addition, as we have seen (§ b.) in the case of the negative index -2 .

§ d. The *arithmetical complement* of a number, is the difference

between that number, and the first number that ends with a cipher, and is one scale higher in the decimal order of notation. The arithmetical complement of 6, is 4, ($10 - 6 = 4$); of 77, is 23, ($100 - 77 = 23$); of 115, is 885, ($1000 - 115 = 885$), etc.

§ c. If it be required to subtract 6 from 9, the result is the same, whether we say $9 - 6 = 3$, or take the arithmetical complement (4) of 6, add it to 9, ($4 + 9 = 13$), and reject the borrowed (10) from their sum ($13 - 10 = 3$).

§ 89. To find the arithmetical complement of a logarithm.

§ a. Prefix (1) to as many ciphers as there are digits in the proposed logarithm; then from this number subtract the proposed logarithm, and the remainder will be the required arithmetical complement.

§ b. Thus, the arithmetical complement of 1.903090 is 8.096910; for 1.903090.

1.903090

8.096910

§ c. The same result may be obtained by beginning at the left, and subtracting from 9, every figure except the last significant one, which must be subtracted from 10.

Thus—

9.9999	(10)0
1.9030	9 0
8.0969	1 0

§ d. If the index be greater than 9, it must be subtracted from 19.

§ 90. To find the logarithm of a decimal fraction.

§ a. The mantissa for the proposed fraction is taken from the table, as for an integral geometrical number of the same significant figures which the fraction has.

§ b. The logarithm for the same figures expressed both integrally and fractionally, differs only in the characteristic; the mantissa is the same in both cases. Therefore we have only to teach how to determine a *positive* characteristic, or the logarithm of a decimal fraction.

§ c. The characteristic is determined by means of the number of ciphers which precede the first significant figure of the decimal, for the number of these subtracted from (9), gives the required characteristic.

Thus, logarithm of the decimal .301 = 9.478567

Logarithm of the decimal .0301 = 8.478567

Logarithm of the decimal .000301 = 6.478567

§ 91. To find the logarithm of a vulgar fraction that is less than unity.

§ a. Take from the tables the mantissa for the numerator, and for the denominator, separately, and as if each were a whole number expressed by the same figures. Then, from the logarithm of the numerator, *plus* 10 to the index, subtracting the logarithm of the denominator, leaves the logarithm of the proposed fraction. Thus,

§ b. To find the logarithm of $\frac{25}{100}$.

$$\text{Logarithm of } 25 = 1.397940$$

$$\text{Logarithm of } 100 = 2.000000$$

$$\text{Logarithm of } \frac{25}{100} = 9.397940$$

To find the logarithm of $\frac{3}{8}$.

$$\text{Logarithm of } 3 = 0.477121$$

$$\text{Logarithm of } 8 = 0.903090$$

$$\text{Logarithm of } \frac{3}{8} = 9.574031$$

§ 92. To find the logarithm of a mixed number.

§ a. If the number proposed (9.05) consist of a whole and a decimal fraction, take from the tables the mantissa for the mixed number as if it were a whole, and then prefix the index, *which expresses one less than the number of digits in the integral part of the mixed number proposed*. Thus, the index of the logarithm for 9.05 is 0, and for 90.5 it is 1; the mantissa (.956649) is the same for each number; because it is taken out for the figures (905) as though they stood for a whole number.

$$\text{Then, the logarithm of } 9.05 = 0.956649$$

$$\text{The logarithm of } 90.5 = 1.956649$$

§ b. But if the proposed mixed number consist partly of a vulgar fraction, let it be reduced to an improper fraction; then find the logarithm of the numerator, and of the denominator, as if they were separately whole numbers; and the remainder of logarithm of the numerator, *minus* logarithm of the denominator, is the required logarithm.

Thus, logarithm $12\frac{2}{3} = 1.102663$; for $12\frac{2}{3}$ reduced to an improper fraction is $\frac{38}{3}$; and

$$\text{Logarithm } 38 = 1.579784$$

$$\text{Logarithm } 3 = 0.477121$$

$$1.102663 = 12\frac{2}{3}$$

§ c. The index to the logarithm of an improper fraction, is always a *proper* index; for the numerator, being greater than the denominator of such a fraction, the logarithm of the latter can be subtracted from that of the former, without borrowing 10 in the index.

§ 93. To find the geometrical number which corresponds to a logarithm.

§ a. The number of digits in the geometrical number for a logarithm, is known by the characteristic of the logarithm; for 1 added to the *characteristic* tells the number of digits.

§ b. Find, in the table, the mantissa of the proposed logarithm. The figures in the first column (N.) being prefixed to the figure that stands at the top of the column in which the mantissa is found, compose the geometrical number that is required.

§ c. The geometrical number of log. 3.759214 = 5744.

The geometrical number of log. 2.759214 = 574.4.

The geometrical number of log. 1.759214 = 57.44.

The geometrical number of log. 0.759214 = 5.744.

This mantissa is found in the column (4) of the table, and opposite to 574 in the first column (N.).

§ d. Had the index of the logarithm been greater than (3), the number of digits for the geometrical number required, would have been made up by affixing ciphers to the numbers (574 and 4) found above, and opposite to, the mantissa. Thus, the geometrical number for 4.976854 is known (§ a.) to consist of five digits, because of the index (4). The mantissa (.976854) is found opposite to 948 (in the column N.), and under 1; making up with ciphers, the proper number of digits.

The geometrical number for 4.976854 = 94810

The geometrical number for 5.976854 = 948100

The geometrical number for 6.976854 = 9481000

§ e. If the proposed mantissa cannot be found in the tables, take that mantissa in the tables, which, being less, comes nearest to it, and affixing any number of ciphers to the difference between these two mantissæ, divide it by the difference between said tabular mantissa and the one next in order after it; the quotient, being affixed to the numbers opposite to, and at the head of the column of, said least mantissa, comprise the figures of the required geometrical number. The digits for the integral part of the geometrical number are determined by the index of the proposed logarithm (§ a.), and the figures which are to the right of these digits, constitute the fractional part of the geometrical number. Thus,

§ f. Geometrical number for 4.979744 = 95443.

Geometrical number for 2.979744 = 954.43.

Geometrical number for 0.979744 = 95.443.

The proposed mantissa (979744) cannot be found in the tables. The difference between the next less (.979730) and the next greater (979776) found in the tables, is 46; and the difference (14) between the less of these two and the proper mantissa being prefixed to any number of ciphers, (14000 - - -), and divided by the tabular difference (46), gives 3 + to be affixed to the four figures 9544, from which the required digits for the integral part of the geometrical number, are to be separated according to the index of the logarithm proposed.

§ g. If the index of the logarithm proposed be an *improper* characteristic, the geometrical number of the logarithm is a decimal fraction. And the difference between this characteristic and (9), tells how many ciphers must intervene between the decimal point (.) and the first significant figure of the fraction. Thus (the indices being *improper*),

The geometrical number for 7.911424 = 0.008155.

The geometrical number for 9.897627 = 0.79.

The geometrical number for 5.698970 = 0.00005.

§ 94. To perform multiplication by logarithms.

§ a. Add the logarithms of the factors together; the sum of these is the logarithm of the product. Thus,

§ b. To multiply 3 by 4; 20 by 2.5; and .25 by .30.

$\begin{array}{r} \text{Logarithm } 3 = 0.477121 \\ \text{“ } 4 = 0.602060 \\ \hline 1.079181 = 12 \end{array}$	$\begin{array}{r} \text{Logarithm } 20 = 1.301030 \\ \text{“ } 2.5 = 0.397940 \\ \hline 1.698970 = 50 \end{array}$
---	--

$$\begin{array}{r} \text{Logarithm } 0.25 = 9.397940 \\ \text{“ } 0.30 = 9.477121 \\ \hline 8.875061 = 0.075 \end{array}$$

§ 95. To perform division by logarithms.

§ a. Subtract the logarithm of the divisor from the logarithm of the dividend, the remainder will be the logarithm of the quotient.

§ b. To divide 36 by 3; 8941 by 19; 50 by .05; and 82.7 by 70.91.

$\begin{array}{r} \text{Log. } 36 = 1.556302 \\ \text{“ } 3 = 0.477121 \\ \hline 1.079181 = 12. \end{array}$	$\begin{array}{r} \text{Log. } 8941 = 3.951386 \\ \text{“ } 19 = 1.278754 \\ \hline 2.672632 = 470.57 + \end{array}$
--	--

$\begin{array}{r} \text{Log. } 50 = 1.698970 \\ \text{“ } .05 = 8.698970 \\ \hline 3.000000 = 1000 \end{array}$	$\begin{array}{r} \text{Log. } 82.7 = 1.917506 \\ \text{“ } 70.91 = 1.850708 \\ \hline 0.066798 = 1.16 + \end{array}$
---	---

§ 96. To perform involution by logarithms.

§ a. Multiply the logarithm of the proposed geometrical number by the index (§ X.) of the power to be involved; this product will be the logarithm of the required power.

§ b. Raise 8^2 17^3 112^4 516^9 .

$\begin{array}{r} \text{Log. } 8 = 0.903090 \\ \quad \quad \quad 2 \\ \hline 1.806180 = 64 \end{array}$	$\begin{array}{r} \text{Log. } 17 = 1.230449 \\ \quad \quad \quad 3 \\ \hline 3.691347 = 4913 \end{array}$
---	--

$$\begin{array}{r} \text{Log. } 112 = 2.049218 \\ \quad \quad \quad 4 \\ \hline 8.196872 = 157351936 \end{array}$$

$$\text{Log. } 516 = 2.712650$$

9

$$24.413850 = 2593267484132083176308736$$

§ c. If the geometrical number that is proposed to be raised, be a decimal fraction, the difference between the characteristic of the logarithm of the power, and the product of 10 by the index of the power involved, expresses *one* more than the number of ciphers, that must precede the first significant figure of the required power.

§ d. To raise .17³ .05³ .064³.

$$\text{Log. } 0.17 = 9.230449$$

3

$$\text{Log. } 0.05 = 8.698970$$

2

$$27.691347 = 0.00491 +$$

$$17.397940 = 0.0025$$

$$\text{Log. } 0.064 = 8.806180$$

5

$$44.030900 = 0.000001073 +$$

§ 97. Evolution is the converse of involution.

§ a. To perform evolution by logarithms.

§ b. The quotient, obtained by dividing the logarithm of the power proposed, by the exponent (§ XII.) of the root to be extracted, is the logarithm of the root required.

§ c. To evolve the square root of 196, the $\sqrt{\quad}$ of 81, and the $\sqrt[3]{\quad}$ of 128.

$$\text{Log. } 196 = 2.292256 \div 2 = 1.146128 = 14.$$

$$\text{Log. } 81 = 1.908485 \div 3 = 0.636161 + = 4.326 +.$$

$$\text{Log. } 128 = 2.107210 \div 7 = 0.301030 = 2.$$

§ d. If the geometrical number whose root is to be evolved, be a decimal fraction, in order to obtain the logarithm of the root required, the exponent, less *one*, of the root to be extracted, must be prefixed to the characteristic of the logarithm of the number proposed; and then the quotient, that arises from dividing this quantity by the exponent of the root to be evolved, will be the logarithm of the power required. Thus, to find the cube root of .27. The logarithmic index of 0.27 is 9; now, to 9, prefixing *one* less (2), than the exponent (3) of the root to be evolved, makes the logarithm of $0.27 = 29.431364 \div 3 = 9.810454 + = 0.646 +$. To find the square root of 0.00776, the logarithmic index of which is (7); prefixing to 7 *one* less (1) than the exponent (2), makes the logarithm of $0.00776 = 17.889862 \div 2 = 8.944931 = 0.088 +$.

§ 98. In the tables (II.) containing logarithms for sines and co-sines,

tangents and co-tangents, the logarithms are calculated from the ratio between the radius and the sine, or the tangent of an arc.

§ a. In these tables, as in all others, the logarithmic value of a sine or a tangent is conventional, as are the logarithms of geometrical numbers.

§ b. In forming these tables, radius is taken as the base, or the ground work for the calculations; and its value is assumed to be 10.000000. The logarithmic value of the sine of 90° , or of the tangent of 45° (§ 62.), shows that this is the value with which radius enters this system. Wherefore, in every calculation, radius = 10.

§ 99. If an arc of 90° , or if a right angle, be divided into any two parts, the sine or the tangent of either part, is the co-sine or co-tangent of the other. Thus, in the quadrant ABC; $AB=30^\circ$; $BC=60^\circ$, $Aa=35^\circ$, and $aC=55^\circ$; PB is the sine of $AB=30^\circ$, and co-sine of $BC=60^\circ$; BS is the sine of 60° (BC), and co-sine of 30° (AB); therefore the co-sine of AB , is BS , which is sine of BC , and the co-sine of BC is Bp , which is sine of AB . In the same manner AH and CD are reciprocally the tangents and co-tangents of Aa and aC . Wherefore the tables, by being calculated as far as 45° , answer for the whole circle, or for two right angles.

§ 100. The logarithmic value of the sec. of an arc, or an angle, is the arithmetical complement of the logarithmic co-sine of the same arc or angle.

§ a. The logarithmic co-sec. is the arithmetical co. of the logarithmic sine, and the logarithmic co-tangent is the arithmetical co. of the logarithmic tangent, and *vice versa* (Vide § 109. § h.).

§ b. Wherefore in logarithmic tables of the trigonometric functions, it is only essential that the logarithms of the sine, co-sine, and tangent, or of the sec., co-sec., and co-tangent, should be given, for the first three are the arithmetical co. of the latter, and *vice versa*; but to facilitate beginners in their calculations, the logarithmic sine, co-sec., co-sine, secant, tangent, and co-tangent, for every degree ($^\circ$) and minute ($'$), are given in the tables (II.), as well as for every hour (h), minute (m), and four seconds (s), of the day.

§ 101. In trigonometrical calculations, when any logarithm is to be subtracted, the proper result may be obtained by adding the arithmetical co. of such logarithm.

§ a. This method of changing subtraction into addition is found very convenient in practice. After a little exercise in it, the arithmetical co. of a logarithm may be read from the logarithm, as readily as the logarithm itself is read from the tables.

§ b. Wherefore in the solution of trigonometrical problems, sub-

traction need never be performed, for (§ 101.) instead of subtracting a logarithm, the same result is obtained by substituting, for this logarithm, its arithmetical co., and adding this arithmetical co. in the calculation; therefore (§ 100. § a.),

When { A logarithmic sine of an arc or an angle is to be subtracted, add its co-sec., and *vice versâ*.
 A logarithmic co-sine of an arc or an angle is to be subtracted, add its sec., and *vice versâ*.
 A logarithmic tangent of an arc or an angle is to be subtracted, add its co-tangent, and *vice versâ*.

§ 102. To find in the tables (II.), the logarithmic value of the sine of an arc or an angle.

§ a. If the proposed arc or angle be an *extreme* one, the number of *degrees* contained in it, is at the top of the page. But if the one proposed be a *mean* arc or angle, the *degrees* contained in it, are to be found at the *bottom* of the page.

§ b. An *extreme* arc or angle is one that contains *less* than 45° , or *more* than 135° . A *mean* arc or angle contains *more* than 45° but *less* than 135° .

§ c. If the proposed arc contain *less* than 45° or 3 H, or having *more* than 90° or 6 H, contain *less* than 135° or 9 H, the odd minutes of it are to be found in the proper minute column at the left of the page. But if it be *greater* than 135° or 9 H, or being *greater* than 45° or 3 H, contain *less* than 90° or 6 H, the odd minutes of it are contained in the minute column, that is at the right hand side of the page.

§ d. The columns marked at the bottom, Cos., Sec., Sin., Co-sec., Co-tang., and Tang., contain the logarithmic co-sine, secant, sine, co-sec., co-tang., and tang., of the degrees, etc., that are at the *bottom* of the page. And those marked Sin., Co-sec., Cos., Sec., Tang., and Co-tang., at the top, contain the logarithmic sine, co-sec., co-sine, secant, tangent, and co-tangent of the degrees, etc., at the *top* of the page.

§ e. To take out of the tables the logarithmic sine of an extreme arc, that is *less* than 45° , say of $34^\circ 40'$. The degrees (34°) of the arc proposed being found at the top of the page, and the minutes ($40'$) in the minute (') column at the left of the page, the logarithm (9.754960) which, in the column of Sin. stands opposite to the minutes ($40'$), is the required logarithm. In the same way the logarithmic co-sine, or tangent, etc., is found in its proper column, and opposite to the given minutes.

Co-sine $21^\circ 14'$ logarithm = 9.969469.

Tangent $19^\circ 56'$ logarithm = 9.559491.

§ f. If the arc ($179^\circ 7'$) proposed be extreme, and *greater* than 135° , the odd minutes ($7'$) must be found in the last minute (') column on the page; the required logarithm (8.187985) is then found opposite, and in the column marked (Sin.) at the top.

§ g. The odd minutes of a mean arc, say $61^\circ 12'$, that is *less* than 90° , are found in the last minute (') column; and those of one, say $114^\circ 59'$, that is *greater* than 90° , are found in the first minute

([']) column of the page; and the character (Sin., Cos., Co-tang.) of the column is taken from the bottom of the page.

Sine $61^{\circ} 12' = 9.942656$.

Co-tangent $114^{\circ} 59' = 9.668343$.

Tangent $114^{\circ} 59' = 10.331657$.

§ *h*. The trigonometric functions of hours, minutes, and seconds, are taken from the tables in the same way.

§ 103. To find the degs. etc. for a log. sine.

§ *a*. The minutes, in the minute ([']) column, which are found opposite to the proposed logarithm, and the degrees, which stand where the column in which the proposed logarithm is found, is marked Sin., are the degrees and minutes required. The same directions answer for taking out the tangent, secant, co-sine, etc., of a logarithm. Thus,

Logarithm 9.627300 sine = $25^{\circ} 5'$ or $154^{\circ} 55'$.

„ 9.956566 cos. = $25^{\circ} 12'$ or $154^{\circ} 48'$.

„ 9.831709 tang. = $34^{\circ} 10'$ or $145^{\circ} 50'$.

„ 9.745494 cos. = $56^{\circ} 11'$ or $123^{\circ} 49'$.

„ 10.377793 tang. = $67^{\circ} 16'$ or $112^{\circ} 44'$.

§ 104. An arc (A B) and its supplement (B C) have the same sine (B H); therefore the same logarithm answers either to the sine of A B or B C. But, for the most part, in calculations, there is some circumstance connected in the operation, which determines

whether an arc or its supplement be required. If not, the case or the solution is called *doubtful*. The same remarks apply to co-sines, secants, tangents, etc.

PLANE TRIGONOMETRY.

PLANE TRIGONOMETRY.

§ 105. Plane trigonometry is that branch of mathematics by which, with certain data, the unknown parts of triangles are determined.

§ a. Plane trigonometry is divided into right, and oblique, angled trigonometry. The solution of right angled triangles pertains to the former; and that of oblique angled triangles to the latter. The methods of solving problems in either, in most cases are similar.

§ 106. Every plane triangle consists of three sides and three angles; which, in a general term, are called *the six parts* of a triangle.

§ a. If the value of any three of these six parts (the *three* angles excepted), be known, the value of every one of the remaining parts is determinable by trigonometrical operations.

§ b. When the angles constitute the only data, the sides cannot be determined (except in *species*); because there may be any number of triangles which are equiangular to each other, and their homologous sides may all be unequal, as the sides of the two triangles under § 73. are.

§ 107. In order to solve a trigonometric problem, the value of three of five parts, viz., two of the angles and the three sides, must be given, and at least *one* of these three parts must be a side.

§ 108. The several combinations of three, which can be formed of five parts, comprise all the cases that are necessary for solving trigonometric problems.

§ a. To one of these every problem in trigonometry resolves itself for solution.

§ b. These several combinations are reduced to *five* cases; viz.,

1st, When two sides and the angle which is opposite to either of them, are given:

2d, When two angles and the side which subtends either of them, are given:

3d, When two sides and the angle which they contain, are given:

4th, When two angles and the side that is between them, are given:

5th, When the three sides are given.

CASE I.

§ 109. Given the sides (c & b) and the angle (B), that is opposite to (b) one of them:

$$c = 450 \text{ yards.}$$

$$b = 600 \text{ yards.}$$

$$B = 74^\circ 49'$$

Required the remaining parts (A , C , & a)?

§ *a*. First, to find the value of C .

By § 74., $b : \text{sine } B :: c : \text{sine } C$;

and substituting for these given parts (b , c , and C), their values, the proportion is, $600 : \text{sine } 74^\circ 49' :: 450 : \text{sine } C$.

$$\text{Log. sine of } 74^\circ 49' = 9.984569$$

$$\text{Logarithm of } 450 = 2.653213$$

$$12.637782$$

$$\text{Logarithm of } 600 = 2.778151$$

$$\text{Log. sine } C = 9.859631 = 46^\circ 22' 15''.$$

§ *b*. The sum of the two angles B and C (§ 32. § *b*.) being subtracted from 180° , gives the remaining angle (A) of the proposed triangle $A B C$. Thus, $B + C = 121^\circ 11' 15'' - 180^\circ = 58^\circ 48' 45'' = A$.

§ *c*. The logarithmic process (§ *a*.) of finding the value of C , might have been abbreviated, and the operation might have been performed entirely by addition. This abbreviation (§ 101.) consists in using the arithmetical complement of the logarithm of the first term in the order of proportion, in the place of said logarithm. This arithmetical complement, added to the logarithm of the second and third terms, gives the logarithm, (rejecting 10 from the index), of the fourth or required term.

§ *d*. When one or more logarithms are to be subtracted in the process of a calculation, the operation may be simplified (§ 88. § *c*.) by substituting for such logarithms, their arithmetical complements (§ 88. § *e*.), and adding these arithmetical complements in the calculation, and then rejecting the borrowed 10 from the index of the sum thus obtained, the remainder is that which would have resulted by adding together the logarithms which were to be added, and then subtracting from their sum, the logarithms which were to be subtracted.

§ *e*. Hereafter, instead of the logarithm of the first term in the order of proportion being used, its arithmetical complement will be adopted in calculation. This substitution of the arithmetical complement renders the arrangement for calculation uniform; for it changes the process of addition and subtraction, into the simple operation of addition.

§ f. Let it be borne in mind that the *arithmetical complement* (§ 88. § d.) of any numerical expression, is obtained, by subtracting the expression proposed from the number which is made by prefixing unity (1) to as many cyphers, as there are figures in said expression. Thus the arithmetical complement of 89 is 11, for 89—100 = 11. Or, the arithmetical complement is obtained by beginning at the left, and subtracting each figure from 9 (§ 79. § c.), except the last significant figure, which must be subtracted from 10. Thus the arithmetical complement of 9.984569 is 0.015431 (what the former wants of 10.000000), and is obtained thus:

$$\begin{array}{r} 9.99999(10) \\ \text{Logarithm } 9.984569 \\ \hline \text{Ar. co. } 0.015431 \end{array}$$

§ g. And the arithmetical complement of 3.450000 (§ f.) is 6.550000, and is obtained thus:

$$\begin{array}{r} 9.9(10)0000 \\ \text{Logarithm } 3.450000 \\ \hline \text{Ar. co. } 6.550000 \end{array}$$

§ h. When the logarithmic index of any of the *trigonometric functions exceeds 9*, the arithmetical complement of such index is the difference between itself and 19, (§ 89. § d.) and consequently the arithmetical complement is found by subtracting said *index* from 19. Thus the logarithmic tangent of 74° is 10.542504, and its arithmetical complement is 9.457496, which is the co-tang. of 74°.

$$\begin{array}{r} 19.99999(10) \\ 74^\circ \text{ log. tang. } 10.542504 \\ \hline \text{Ar. co. } 9.457496 \end{array}$$

§ i. To find the value of the side *a*; according to § 74, sin. B : *b* :: sin. A : *a*; or, substituting their values, sin. 74° 49' : 600 :: sin. 58° 48' 45'' : *a*.

$$\begin{array}{r} \text{Log. sine } 74^\circ 49' \text{ ar. co.} = 0.015431 = \text{co-sec. B } (\S 100. \S a) \\ \text{Logarithm } 600 \quad \quad \quad = 2.778151 \\ \text{Log. sine } 58^\circ 48' 45'' \quad \quad = 9.932208 \end{array}$$

$$\text{Log. } a = 2.725790 = 531.8 \text{ yards.}$$

The 10, which was borrowed for the arithmetical complement of the logarithmic sine of 74° 49', being rejected in the sum, gives 2 for the index of the logarithmic value of *a*.

§ j. In the solution of all trigonometric problems by calculation, the *logarithmic* values of the functions employed are always used;

therefore the repetition of the word *log.* before *sine*, *tangent*, etc., will be omitted; and the arithmetical complement of the logarithm of a function or number, is that which is to be understood, and not the arithmetical complement of the number itself.

CASE II.

§ 110. Given two angles (A & C) and the side (c) that subtends one of them.

$$A = 23^{\circ} 56'$$

$$C = 76^{\circ} 4'$$

$$c = 1760 \text{ feet.}$$

To find the other parts (B, a and b),

§ a. The process of solution in this case is a repetition of the methods shown § 109. § b. & § i.; for $A + C$ subtracted from 180° (§ 32. § b.) gives $B = 80^{\circ}$; and (§ 74.) $\sin C : c :: \sin A : a :: \sin B : b$.

§ b. To find a. $\sin. 76^{\circ} 4' : 1760 :: \sin. 23^{\circ} 56' : a$.

$$\text{Sine } 76^{\circ} 4' \text{ ar. co.} = 0.012970 = \text{co-sec. } C. (\S 101. \S b.)$$

$$\text{Log. } 1760 = 3.245513$$

$$\text{Sine } 23^{\circ} 56' = 9.608177$$

$$\text{Log. } a = 2.866660 = 735.6 \text{ feet.}$$

§ c. To find b. $\sin. 76^{\circ} 4' : 1760 :: \sin. 80^{\circ} : b$.

$$\text{Sine } 76^{\circ} 4' \text{ ar. co.} = 0.012970 = \text{co-sec. } C$$

$$\text{Log. } 1760 = 3.245513$$

$$\text{Sine } 80^{\circ} = 9.993352$$

$$\text{Log. } b = 3.251835 = 1785.8 \text{ feet.}$$

§ d. If, with similar data, the proposed, be a right angled triangle, the problem may be solved as the one above is, by means of the proportion between the sides and sines of opposite angles; or it may be solved by means of the principles involved (§ 75.) in the proportion between the sides and trigonometric functions of a right angled triangle. Thus, the data being,

$$C = 67^{\circ} 19'$$

$$c = 1760 \text{ feet.}$$

The value of A is known by the rectangularity of the proposed triangle (D A C). To find the other parts (D, d & a),

§ e. The third angle (D) is *always* known (§ 32. § b.) by subtracting the sum of the two other angles from 180° ; $A + C - 180^\circ = D$, or $22^\circ 41'$.

§ f. To find the two sides a and d ; making D A radius, the following proportions (§ 75. § c.) are deduced, viz.:

Rad. : $c :: \text{tang. D} : d$; and Rad. : $c :: \text{sec. D} : a$.

Radius (*always*, § 98. § b.) = 10.000000

$c = 1760 \text{ log.} = 3.245513$

$D = 22^\circ 41' \text{ tang.} = 9.621142$

Log. $d = 2.866655 = 735.6 \text{ feet.}$

Radius = 10.

$c = 1760 \text{ log.} = 3.245513$

$D = 22^\circ 41' \text{ sec.} = 0.034963$

Log. $a = 3.280476 = 1907.5 \text{ feet.}$

CASE III.

§ 111. Given two sides (b & a) and the angle (C) they contain;

$b = 479 \text{ fathoms.}$

$a = 419.8 \text{ ''}$

$C = 119^\circ 41'.$

To find the other parts (A, B & c),

§ a. The solution of this problem is founded

upon § 77.

§ b. One angle (C) of the proposed triangle being known, the sum of the two other angles (A & B) (§ 32. § b.) is obtained by subtracting the given angle from 180° . Thus, $180^\circ - 119^\circ 41' = 60^\circ 19'$, the sum of A & B.

§ c. To find the values of A and B; according to § 77., $(b + a) :$

$\text{tang. } \frac{A+B}{2} :: (b \oslash a) : \text{tang. } \frac{A \oslash B}{2}$. Therefore, by substitution,

$898.8 : \text{tang. } 30^\circ 9' 30'' :: 59.2 : \text{tang. } \frac{A \oslash B}{2}$.

$(b + a) = 898.8 \text{ log. ar. co.} = 7.046337$

$(A + B) + 2 = 30^\circ 9' 30'' \text{ tang.} = 9.764207$

$(b \oslash a) = 59.2 \text{ log.} = 1.772322$.

Tang. $\frac{A \oslash B}{2} = 8.582866 = 2^\circ 11' 30''.$

Now half the difference ($2^{\circ} 11' 30''$) between A and B, being added to half their sum ($30^{\circ} 9' 30''$) (§ 78. § h.), gives B the greater angle; and being subtracted from said half sum, gives A the less angle. Thus $30^{\circ} 9' 30'' + 2^{\circ} 11' 30'' = 32^{\circ} 21'$, or B; and $30^{\circ} 9' 30'' - 2^{\circ} 11' 30'' = 27^{\circ} 58'$, or A. A is known to be the less angle (§ 63.), because its subtending side (a) is the less of the sides b & c .

§ d. The angles and two sides being known, the value of the third side (c) is deducible by means of calculations conducted upon the proportion (§ 74.) between the sides and sines of the angles of plane triangles.

§ e. To find c . $\text{Sin. B} : b :: \text{sin. C} : c$.

$$B = 32^{\circ} 21' \text{ sin. ar. co.} = 0.271573 = \text{co-sec. B} \text{ (§ 100. § a.)}$$

$$b = 479 \text{ faths. log.} = 2.680336$$

$$C = 119^{\circ} 41' \text{ sin.} = 0.988908 \text{ (§ 102. § g.)}$$

$$\text{Log. } c = 2.890817 = 777.7 \text{ faths.}$$

§ f. If the problem comprise a right angle triangle, with similar data, the process of solving it is much more simple. For the two legs and the right angle being the given parts, the calculations for determining the unknown parts, are founded upon the relations of the sides and trigonometric functions of a right angled triangle, as they are shown § 75.

§ g. In the proposed triangle (D B C), right angled at B, the values of the legs, are;

$c = 479$ faths.; and $d = 419.8$ faths.; to find the other parts.

§ h. Making either leg (c) radius, (§ 75. § c.) the terms and order of the proportion for finding the value of D, are, $c : \text{rad.} :: d : \text{tang. D}$. And for finding the hypotenuse (b) they are, $\text{rad.} : c :: \text{sec. D} : b$.

§ i. To find D.

$$c = 479. \text{ Log. ar. co.} = 7.319664$$

$$\text{Radius} \quad \quad \quad = 10.$$

$$d = 419.8 \text{ log.} = 2.623042$$

$$\text{Tang. D} = 9.942706 = 41^{\circ} 13' 53''$$

§ j. To find b .

$$\text{Radius} \quad \quad \quad = 10.$$

$$c = 479 \text{ log.} = 2.680336$$

$$D = 41^{\circ} 13' 53'' \text{ sec.} = 0.123777$$

$$\text{Log. } b = 2.804113 = 636.9 \text{ faths.}$$

CASE IV.

§ 112. Given two angles (A & C) and the side (b) between them;

A = 26° 1'

C = 38° 49'

b = 179 chains,

To find the values of the other parts (B, c & a) of the proposed triangle. (A B C).

§ a. Two angles being known, the third (B) (§ 32. § b.) is also known; it is B = 115° 10'.

§ b. The remaining unknown parts (a & c) of this triangle, are determined by means of the principles involved in the solution of the problem under Case 2. The process of operation in the solution of this, is precisely similar to that of § 109. § i. under Case 1. In the method of their solution, Cases 1, 2, and 4, are only repetitions of each other. For whenever two angles of a triangle are given, the third is also known (§ 32. § b.); and whenever an angle and its subtending side are two of the known parts, the required parts are determinable through calculations conducted upon the proportion (§ 74.) which exists between the sides and sines of angles in all triangles.

§ c. To find the value of a. Sin B : b :: sin. A : a.

B = 115° 10', sin. ar. co. = 0.043316 = co-sec. B (§ 101. § b.)

b = 179 chains log. = 2.252853

A = 26° 1', sin. = 9.642101

Log. a = 1.938270 = 86.7 chains.

§ d. To find the value of c. Sin. B : b :: sin. C : c.

B = 115° 10' co-sec. = 0.043316

b = 179 chains log. = 2.252853

C = 38° 49' sin. = 9.797150

Log. c = 2.093319 = 123.9 chains.

§ e. Transferring the conditions of this problem to one in right angled trigonometry, the use of sines may be retained in the calculation for determining the unknown parts (c & d); for by making the given side (b), radius to an arc (CH), the two legs of the proposed triangle (D B C)

become (§ 75. § a.) sine and co-sine to the acute angles (D & C);

and (§ 75. § b.) rad. : b :: sin. D : d :: co-sine D : c . The parts given are $D = 26^\circ 1'$, and $b = 179$ chains.

§ f. To find the values of c and d .

Radius	-	-	=	10.
$b = 179$.	log.	=	2.252853	
$D = 26^\circ 1'$	sin.	=	9.642101	

$$\text{Log. } d = \underline{\underline{1.894954}} = 78.5 \text{ chs.}$$

	Radius	=	10.
$b = 179$	log.	=	2.252853
$D = 26^\circ 1'$	cos.	=	9.953599

$$\text{Log. } c = \underline{\underline{2.206452}} = 160.8 \text{ chains.}$$

§ g. The same result may be obtained by making a radius of either leg (c), and introducing different trigonometric functions into calculation, upon the principles shown under § 75. § c. Thus; sec. $D : b ::$ radius : $c ::$ tang. $D : d$.

§ h. To find c and d by this method of calculation :

$D = 26^\circ 1'$	sec. (ar. co.)	=	9.953599 = cos. D (§ 101. § b.)
$b = 179$ chains	log.	=	2.252853
Radius	-	-	= 10.

$$\text{Log. } c = \underline{\underline{2.206452}} = 160.8 \text{ chains.}$$

$D = 26^\circ 1'$	cos. (§ 101. § b.)	=	9.953599
$b = 179$ chains	log.	=	2.252853
$D = 26^\circ 1'$	tang.	=	9.688502

$$\text{Log. } d = \underline{\underline{1.894954}} = 78.5 \text{ chains.}$$

§ i. The use of sine and co-sine as functions in plane trigonometrical calculations, being more convenient than that of other functions, the former (§ f.) is generally preferable to the latter method (§ h.) of solving problems.

CASE V.

§ 113. Given the three sides (BC, b, c)

BC = 144 chains.

b = 220 chains.

c = 103 chains.

To find the angles

(C, A & B)

§ a. Here is the application to practice of the principles involved in § 79. And in order to determine the value of any one (C) of these angles by calculation, the distance (a a') from the middle (a) of the base (CB), to the perpendicular (A a') upon

it, must be found by means of the proportion, (§ 79.) the base BC : b ∞ c :: b + c : 2 a a'. Then either of the segments (C a') is found (§ 79. § d.) by applying (C a) half the base (CB) to (a a') the distance of the perpendicular at a' from the middle of the base. This segment (C a'), the perpendicular (A a'), and the side (b), adjacent to the required angle (C), form a right angled triangle (C A a'); of which are known the hypotenuse (b) and a leg (C a').

§ b. The value of the required angle (C) is then found according to the principles established under § 75. For by making the hypotenuse (CA) radius, the segment (C a') becomes co-sine to the required angle (C); the value of which may then be determined (§ 75. § b) by means of the proportion, b : radius :: C a' : cos. C.

§ c. Knowing the value of any one (C) of the angles, either of the others (A) may then be determined by means of calculations conducted upon the proportion (§ 74.) of the sides of triangles to the sines of their opposite angles. And the remaining angle (B) (§ 32. § b.) is determinable by subtraction.

§ d. To find the value of the angle C.

1st. Call CB the base, in order to find twice the distance (a a') from the middle of the base, to a perpendicular drawn upon the base, from its opposite angle (A) (§ 79.). Twice the length of this distance (a a') is evolved by the proportion; CB : b ∞ c :: b + c : 2 a a'.

$$CB = 144, \log. \text{ ar. co.} = 7.841637$$

$$b \infty c = 117, \log. = 2.068186$$

$$b + c = 323, \log. = 2.509203$$

$$\log. 2 a a' = 2.419026 = 282.4$$

L

2d. To find the greater segment $C a'$. One half of 262.4 ($2 a a'$) is equal to the distance ($a a'$) of the perpendicular from the middle of the base; and (§ 79. § d.) $a a' + \frac{B C}{2} = C a'$. Therefore, $131.2 + 72 = C a' = 203.2$.

§ e. If twice the distance ($a a'$) of the perpendicular from the middle of the base be *greater* than the base, the perpendicular falls *without* the triangle, as in the case before us. But if it be *less* than the base, the perpendicular falls *within* the triangle.

To find the value of C . According to § b. we have, $b : \text{rad.} :: C a' : \cos. C$.

$$b = 220. \text{ log. ar. co.} = 7.657577$$

$$\text{Radius} = 10.$$

$$C a' = 203.2 \text{ log.} = 2.307924$$

$$\text{Cos. } C = 9.965501 = 22^\circ 32' 11''$$

§ f. To find the value of A (§ c.) we have, $c : \sin. C :: B C : \sin. A$.

$$c = 103. \text{ log. ar. co.} = 7.987163$$

$$C = 22^\circ 32' 11'' \text{ sine} = 9.583504$$

$$B C = 144. \text{ log.} = 2.158363$$

$$\text{Sine } A = 9.729030 = 32^\circ 24' 2''$$

§ g. To find the value of B . According to § 32. § b. $C + A - 180^\circ = B$; therefore $B = 125^\circ 3' 47''$.

§ h. If, when the perpendicular falls *without* the triangle, the obtuse angle (B) be the first part required, the side (c) adjacent to it becomes hypotenuse to the right angled triangle, of which, the perpendicular to the base and the smaller segment ($B a'$) of the base, are legs, and the supplement ($A B a'$) of the required angle (B) is that which is evolved from the proportion (§ b.), $c : \text{rad.} :: B a' : \cos. A B a'$.

EXAMPLE I.

§ 114. A rock is seven miles from a light-house, and a ship, having the light-house to bear E. by N., is nine miles S. W. of the rock; What is the distance between the ship and the light-house?

Ans. 12.4 miles.

§ a. The solution of this problem is conducted after the methods shown under § a. and § i. (§ 109.) The parts given are the sides a and c , and the angle (A) contained at the ship, between the bearing of the rock and light-house. The value of A is known by converting into degrees, etc., the points contained between the bear-

ing of the rock and light-house, from the ship. The rock bears N. E., and the light-house E. by N. from the ship. Three points intervene between E. by N. and N. E., and each point contains $11^{\circ} 15'$; therefore the angle (A) contained between the lines of these bearings is $11^{\circ} 15' \times 3$, or $33^{\circ} 45'$.

§ b. Unless the problem were embraced in a right angled triangle, the value of C must be found, and B known (§ 32. § b.) before that of b is determined. C is found (§ 109. § b.) from the proportion (§ 74.) which exists between certain parts of every triangle; viz., $a : \sin. A :: c : \sin. C$. Then $C + A - 180^{\circ} = B$; and then, $\sin. C : c :: \sin. B : b$, affords the solution required.

EXAMPLE II.

§ 115. A ship was steering N. and sailing 10 knots per hour; she made a point of land bearing N. E. by N.; two hours afterwards the same point bears E. by S. What is the distance of it from the ship?

Ans. 12. + miles.

§ a. The solution of this problem depends upon the principles which Example 1 involves. The angle (A) between the point of land and the ship's course is three points, or $33^{\circ} 45'$. The angle (C) between the bearing of the ship from the point of land at each station, is six points, or $67^{\circ} 30'$. And the angle (B) between the second bearing of the land and the line upon which the ship sailed,

is seven points, or $78^\circ 45'$; or it is $A + C - 180 = 78^\circ 45'$. Then the proportion of $\sin. C : c :: \sin. A : a$, determines the value of the part required.

EXAMPLE III.

§ 116. Several boats, intending to cut a ship out from under the guns of a castle, wish to know how far she is off from the castle, which bears N. $\frac{1}{4}$ E. 917 fathoms from a watch-tower, that is 491 fathoms N. W. from the ship.

Ans. 1285.7 fathoms.

§ a. The solution of this problem involves in it the principles demonstrated § 77, by which either angle (B or C) is found; and then the length of the required side (a) is determined by the ratio between the sides and sines of opposite angles.

§ b. The parts given are, the distances (b & c) of the watch-tower (A) from the ship and castle, and the angle (A) contained at the watch-tower between the lines of bearing from it to the castle and ship. The angle (A) at the watch-

towr contains $11\frac{1}{2}$ points, or $129^\circ 22' 30''$. The sum of the angles B and C is found by subtracting A (§ 32.) from 180° . And half their difference is determined by the proportion (§ 77.), $b+c :$

$$\text{tangent } \frac{B+C}{2} :: b \propto c : \text{tang. } \frac{B \propto C}{2}.$$

§ c. The value of B and of C is then known by § 77. § h.; and the solution completed by evolving the value of a from the proportion,— $\sin. C : c :: \sin. A : a$.

EXAMPLE IV.

§ 117. Wishing to know the height of a Chinese pagoda that stood in a plane, I took the altitude of the sun from an artificial horizon, and at the same time the length of the shadow cast by the pagoda was marked and measured.

The sun's corrected altitude was $21^\circ 10'$.

The length of the shadow 347 feet.

Ans. Height of pagoda 134.3 feet.

§ a. The pagoda is supposed to stand upright. The angle (A) which is formed at the end of the shadow by an imaginary line drawn thence to the top of the pagoda, is $21^\circ 10'$, or whatever be the altitude of the body which

causes the shadow. The solution of this problem may be conducted according to the principles shown § 75. § c.

§ b. The parts given are the length (c) of the shadow, the angles A and B. The latter is known from the primitive condition of the triangle, which is right angled.

§ c. Making the given leg radius, the other leg (a) or height of the pagoda, becomes tangent to the angle (A) of altitude. The value of the required part (a) is evolved by means of the proportion, $\text{rad.} : c :: \text{tang. } A : a$.

EXAMPLE V.

§ 118. A road crosses a mountain, the base of which is nine miles across. The distance from the foot to the top of the mountain, is 4.5 miles on one side, and 5.3 on the other.

What is the angular ascent of the road on each side of the mountain, and how high is the top above the base ?

Ans. Angle of ascent on one side = $31^\circ 32' 21''$

Angle of ascent on the other = $26^\circ 32' 25''$

Height of the mountain 1.94 miles.

§ a. This problem involves in the solution of it, the principles

demonstrated § 79. and § 75. The parts given are the three sides (a, b, c).

§ b . The operation for finding the ascent of the road, or the angles A and C , is a repetition of the method shown in Case 5, § 113, for finding C and B . Bp , the perpendicular upon the base (b) of the mountain, shows its height; the value of it is determined (§ 75.) after the angles A & C are determined. $AC : c \cos a :: c + a : 2pb$; and (§ 79. § d .) $pb + \frac{AC}{2} = pC$; and (§ 75. § b .) $a : \text{rad.} :: pC : \cos. C$; and (§ 74.) $c : \sin. C :: a : \sin. A$; and $\text{rad.} : a :: \sin. C : Bp$.

EXAMPLE VI.

Wishing to ascertain the breadth of a river, I observed that a cocoa-nut tree, which stood at the water's edge on the opposite bank, bore west of me; then after having walked due south 194 yards, the same tree bore N. W.

How wide was the river?

Ans. 194 yards.

EXAMPLE VII.

Wishing to know the height of a mountain in South America, on the morning of the 22d December, 1832, between eight and nine o'clock, I measured with a sextant the altitude of the sun above the top of the mountain; it was $19^\circ 40' 15''$. The apparent altitude of the sun, measured at the same time from an artificial horizon, was $41^\circ 47' 45''$. Then going from the mountain, I measured 4420 fathoms, and the next day, when the top of the mountain was again in the plane of the sun's azimuth circle, the sun's altitude above the top of the mountain, and from an artificial horizon taken as before, was, from the horizon = $40^\circ 21' 30''$, above the mountain = $25^\circ 14'$

What is its height?

Ans. 3564.1 fathoms, or 21384 feet 7 inches.

EXAMPLE VIII.

Supposing that a ray of light is not refrangible, that the earth is a perfect sphere, that its diameter is 7924 miles, and that the height of Chimborazo is 21384 feet, How far can the top of this mountain be seen from the surface of the earth?

* The mean diameter of the earth is about 7923.57 miles.

SPHERICS.

SPHERICS.

§ 119. Spherical Trigonometry is one of the principal branches upon which the science of navigation is founded. The solution of all problems for finding latitude, longitude, variation, etc., from data obtained by means of observations made upon celestial objects, depends upon the principles of spherical trigonometry.

§ *a*. As the figure of the earth is an approximation to that of a sphere, the whole science of navigation, properly speaking, is based upon the doctrines of the sphere.

§ 120. The figure of a *sphere* may be generated by the revolution of a semicircle about its diameter, as an axis. A perfectly round globe or ball is a sphere.

§ 121. Trigonometrically speaking, all lines upon a sphere are curved lines. These lines are either circles, or arcs of circles. Circles are either *great* or *small*.

§ 122. A *great circle* is concentric with the sphere.

§ *a*. The shortest distance between two points on a plane (§ 3.) is the straight line that joins them; and the shortest distance on a sphere, between two points, is the arc of a great circle, that joins them.

§ *b*. Every great circle has two *poles*.

§ 123. The *poles* of a great circle are two points on the surface of a sphere, that are diametrically opposite to each other, and are equidistant from all points at the circumference of their circle. Consequently each pole is 90° from the circumference of its circle.

§ *a*. The north and south poles are the poles of the equator. The equator is 90° from either pole.

§ 124. The straight line, which, passing through the centre of a great circle, joins its poles, is the *axis* of that circle.

§ 125. All great circles cross each other in points diametrically opposite. Therefore,

§ *a*. Two great circles cannot be parallel; but they divide each other into arcs of 180° each.

§ *b*. The space contained between the intersecting halves of two great circles, is called a *lune*.

§ 126. One great circle is perpendicular to another, when the two cross each other at right angles.

§ *a*. When two great circles cut each other at right angles, the axis of either lies along the plane of the other; and they pass through the poles of each other.

§ 127. A *secondary* is a great circle that crosses another, perpendicularly.

§ *a.* A meridian of longitude is secondary to the equator.

§ 128. Every great circle divides its sphere into two equal parts, as the Equator does the earth.

§ 129. A *small circle* divides the sphere into two unequal parts; as the Tropic of Cancer, or of Capricorn, or as a parallel of latitude, does the earth.

§ *a.* If every point at the circumference of a small circle be equidistant from either pole of a great circle, the small is parallel to the great circle.

§ *b.* The centre of a small circle is in the axis of the great circle to which it is parallel.

§ 130. The radius of a small circle, is the sine of the arc intercepted between its circumference and the pole of the great circle, to which it is parallel.

§ *a.* The radius of a parallel of latitude is the co-sine of its own latitude.

§ 131. All spheric, like all rectilineal, angles, are either acute right, or obtuse; and their values are expressed under the same denominations of degrees ($^{\circ}$), minutes ($'$), and seconds ($''$).

§ 132. Two arcs of great circles, like two straight lines, (§ 25 & § 27.) that cross each other, make the vertically opposite angles equal to each other, the two angles that are on the same side of either, equal to two right angles, and the four angles together equal to four right angles.

§ 133. A spherical angle is at the pole of the circle, upon which it is measured.

§ *a.* And the arc of this circle, which is intercepted between the two arcs forming the angle, is its measure.

§ *b.* The two circles which form an angle are secondaries (§ 127.) to that upon which the angle is measured.

§ *c.* This circle (§ 126. § *a.*) passes through the poles of its secondaries.

§ *d.* The distance between the poles of two great circles that form an angle with each other, measures that angle.

§ 134. Every spherical, like every plane triangle, has three sides and three angles, and any two of the former are greater than the third.

§ 135. The sides of a spherical triangle are arcs of circles. Their values are *always* expressed in degrees ($^{\circ}$), minutes ($'$), and seconds ($''$).

§ 136. Plane triangles are unlimited as to the value of their sides; the sum of the three sides of a spherical triangle is less than 360° . For if two arcs that form an angle be each 180° , they will intersect each other (§ 125.) in another point, that is diametrically opposite to their angular point; then, if a third arc cross these two, it will divide the lune (§ 125. § *b.*) into two triangles, and be a side to each. This third side is less (§ 134.) than the sum of the two other sides of either triangle, and the sum of these four sides, by supposition,

is two semicircles, or equal to 360° ; therefore the sum of the two sides of either triangle plus the third side is *less* than 360° ; and so with any spherical triangle.

§ a. The minimum of the sides of a spherical triangle is without limits.

§ 137. The sum of the angles of a plane triangle is equal to two right angles; the sum of the angles of a spherical triangle, in all cases, is greater than two, but less than six, right angles.

§ a. The exterior angle of a spherical triangle (§ 132.), therefore is not, as in a plane triangle, necessarily equal to the sum of the two remote interior angles of the triangle.

§ b. Most of the other propositions of elementary geometry which show the ratio, relations, or equality between the parts of plane triangles, are likewise applicable to spherical triangles.

§ 138. Two angles, or two legs, of a spherical triangle, are *alike*, or of the *same affection*, when both of them are either acute or obtuse.

§ 139. In spherical, as in plane triangles (§ 63.), the greatest side and angle subtend each other; so also do the mean and least.

§ a. An angle and its opposite side are not always of the same affection.

§ 140. Spherical, besides being, as plane triangles, divided into equilateral, isosceles, and scalene, are either right angled, quadrantal, or oblique.

§ 141. A *right angled spherical triangle* has one right angle.

§ a. The side subtending the right angle is the hypotenuse; but it is not, as in a plane triangle, necessarily the greatest side.

§ b. If the hypotenuse be less than 90° , the legs are of the same affection; and the oblique angles also.

§ c. If the hypotenuse be greater than 90° the legs are unlike, and the oblique angles also.

§ d. A leg of a right angled spherical triangle, and its opposite angle, are always of the same affection.

§ 142. A *quadrantal triangle* has a side that is a quadrant, or 90° .

§ 143. An *oblique spherical triangle* has neither a side, nor an angle of 90° .

§ 144. In plane triangles, the sides, and the sines of their opposite angles, have the same ratio to each other; in spherical triangles, the sines of the opposite sides and angles are proportional.

§ 145. In plane triangles (§ 107.), one side, at least, must be among the three parts that constitute the data necessary for finding the other parts; in spherical triangles any three parts are data sufficient for determining the other parts. Therefore—

§ 146. In spherical trigonometry, the three sides of a triangle can be determined by having the three angles as data; and the reverse.

§ 147. For the purpose of facilitating, by logarithmic calculation, the solution of problems in spherical trigonometry that are included in oblique triangles, spherical trigonometry is here divided into right and oblique angled trigonometry.

§ *a*. All the problems that come under the several cases, two excepted, of oblique spherical trigonometry, may be solved by reducing them to analogous cases in right angled trigonometry; this is done by means of drawing a perpendicular from an angle upon its subtending side, of the proposed triangle, and from such an angle, that the proposed oblique triangle will be divided into two right angled triangles, one of which shall contain two of the parts given in the problem.

§ 148. Every problem in oblique trigonometry may be solved without the direct intervention of a perpendicular, and of right angled triangles.

§ *a*. The process of calculation is shortened by solving the problems without conducting the operation upon the principles of right angled triangles. For this reason spherical trigonometry is here divided into right and oblique trigonometry.

§ 149. Problems comprising as data the three angles, or the three sides of an oblique triangle, do not admit of the intervention of right angles for determining the unknown parts; because, in neither case can a perpendicular be so drawn in the proposed triangle, that two of the given parts will fall in either of the right angled triangles, or on either side of the perpendicular.

§ 150. By some, problems that depend upon quadrantal triangles, are included in a separate division of spherical trigonometry, called "quadrantal trigonometry." But knowing three parts, the other three of a quadrantal triangle may be determined by the rules for finding with similar data, like parts that are unknown in a right angled triangle.

§ *a*. In arranging for calculation the trigonometric functions of the parts in a problem included in a quadrantal triangle, the legs must be called *angles*, and their adjacent angles, *legs*; the *supplement* of the angle that subtends the quadrantal side, must be called the *hypotenuse*, and the quadrantal side, *radius*.

§ 151. The side and angle that are opposite in a quadrantal triangle, are of the same affection.

§ 152. The relations between the parts of a triangle in plane, and the parts of a triangle in spherical, trigonometry, are similar; and the formulæ for the solution of problems in the one, are analogous to the formulæ for the solution of similar problems in the other.

§ *a*. As much, with regard to the sides, can be determined from the three angles of a plane triangle, as can be determined from the three angles of a spherical triangle. In the former case, the triangle can be determined in *species*; and in the latter, the sides are determined in degrees and minutes of arcs, which arcs, in *absolute* length, may be infinitely great or small. And the number of miles, or of any units of a positive quantity, contained by any one of these arcs, depends upon the relations of other quantities to it, and not at all upon the relations between it and the other parts of its triangle.

§ *b*. In order then to arrive at absolute values for the sides and angles of a triangle which are submitted for calculation, a third

quantity, that will answer the purpose of a common measure for lines and angles, or arcs, must be brought into consideration.

§ c. And this common measure is the *radius* of a circle. When we say that a side of a spherical triangle is an arc containing a certain number of degrees and minutes, we have no reference to the *absolute* length of this arc, or to the number of inches, or fathoms, or miles, contained in it. It may be an arc whose radius is infinitely great or small. But if the length of its radius in inches, or miles, be known, the *absolute* length of the arc also in the denominations of the same dimensions is determinable. But this belongs to another branch of mathematics, which is not relevant to the purposes for which this treatise is designed.

§ 153. The analogy between the formulæ for the solution of problems of like data and quæsitæ in plane and spherical trigonometry, grows out of the resemblance between the parts of a plane and a spherical triangle.

§ a. Suppose that the sides of a spherical triangle should remain of the same *absolute* length, and that the radius of their sphere be increased *ad infinitum*. The angles at the centre of the sphere, which these sides subtend, and the number of degrees contained in these sides, or arcs, will be decreased until they reach the *ultimatum*, when the surface included by these three sides becomes a plane, the triangle a plane triangle, and a *finite* portion of infinity.

RIGHT ANGLED SPHERICAL TRIGONOMETRY.

§ 154. In the trigonometrical solution of right angled spherical triangles, there are *five parts*, (three sides and two angles,) any one of which may be the unknown and required part of the problem.

§ a. The right angle is ever known from the condition of the triangle. In calculation the right angle is not called a *part*.

§ 155. Any two of the five parts of a right angled spherical triangle being known, the rest are determinable by means of trigonometrical calculations.

§ 156. In right angled spherical trigonometry, there can be six cases of two different parts as data, viz.:

1. The hypotenuse and a leg.
2. The hypotenuse and an angle.
3. The two legs.
4. The two angles.
5. An angle and its opposite leg.
6. A leg and its adjacent angle.

§ 157. Lord Napier has given *two rules*, by which every problem that can occur in any of these several cases, may be solved. But he has not made known the process of reasoning, by which he arrived at the conclusions, whence he deduced these rules; nor have mathematicians been able to follow the steps of this bold reasoner.

§ a The truth of his, called the Catholic Proposition, is sufficiently

established by practice, and by its utility, and may therefore be admitted as an axiom or received truth.

§ 158. In his Analytical Treatise on Plane and Spherical Trigonometry, Dr. Lardner observes, "We have thus established *Napier's rules*, by proving separately all the several cases which they include. There is no independent or general demonstration of these remarkable theorems, nor is it easy to conceive the process of mind by which their illustrious inventor arrived at them. Professor Woodhouse justly observes, that there are not, perhaps in the whole compass of mathematical science, rules which more completely attain that which is the proper object of rules, namely, brevity and facility of computation. He might have added, that few, or perhaps no theorems equally general, make such an immediate and permanent impression on the memory."*

§ 159. The *five* parts of a right angled triangle, are called, in *Napier's rules*, the *circular* parts.

§ a. The circular parts are the two legs, and the *complements* of the hypotenuse and its adjacent angles, instead of these three parts themselves.

§ 160. The right angle (§ 154. § a.) is thrown out of consideration; and the five circular parts join each other.

§ a. The complement of the hypotenuse joins the complement of each of the two angles; each of which angular complements joins its adjacent leg, and the two legs join each other.

§ 161. In every problem two of these parts are given and a third is sought. They are named from their relative position with regard to each other.

§ a. One of them is the *middle* part; the two others are *extremes*, either *conjunct* or *disjunct*.

§ 162. If the parts given and the part sought join each other in circular order, the first and last in this order are called *extremes conjunct*; and the part between them connects them together, and is called the *middle* part.

§ a. The triangle A B C, represents a right angled spherical triangle, right angled at A; its hypotenuse is *a*, and *b* & *c* are its two legs. The circular parts are the leg *b*, the complement of C, do. of *a*, do. of B, and the other leg *c*.

§ b. The three parts, *a*, B, *c*, join in circular order. The complement of B is the connecting part between *c* and the complement of *a*. The complement of B is the middle part; *c*, and the complement of *a*, are extremes conjunct.

§ c. Of the parts	Middle part is,	Extremes conjunct are,
B, <i>c</i> , <i>b</i> .	<i>c</i> .	<i>b</i> , and complement of B.
<i>c</i> , <i>b</i> , C.	<i>b</i> .	<i>c</i> , and complement of C.
<i>b</i> , C, <i>a</i> .	Complement of C.	<i>b</i> , and complement of <i>a</i> .
C, <i>a</i> , B.	Complement of <i>a</i> .	Complements of C and B.
<i>a</i> , B, <i>c</i> .	Complement of B.	<i>c</i> , and complement of <i>a</i> .

* See Analytical Treatise on Plain and Spherical Trigonometry, by the Rev. Dionysius Lardner.

§ 163. If the parts given, and the parts sought, be not adjacent to each other in the circular order, that part which stands alone, or is not adjacent to either of the two other parts, is the middle part, and the two others are *extremes disjunct*.

§ a. The three parts, a, c, b , do not join each other in the circular order; the complement of a is not adjacent to either of the two other parts, being separated from them by the complement of the two acute angles, C & B ; it stands alone, and is therefore (§ 163.) the middle part, and the two other parts that do join each other, are the *extremes disjunct*.

§ b. Of the parts	Middle part is,	Extremes disjunct are,
$B, b, C.$	Complement of $B.$	b , and complement of $C.$
$c, C, a.$	$c.$	Complements of C and $a.$
$c, C, B.$	Complement of $C.$	c , and complement of $B.$
$b, a, B.$	$b.$	Complements of B and $a.$
$a, c, b.$	Complement of $a.$	b and $c.$

§ 164. Napier's rules establish an equality of ratio between radius, the *sine* of the middle part, and certain trigonometric functions of the *extremes*. They are,

§ 165. The product of radius and sine of the middle part, is equal to the product of the tangents of extremes conjunct. And,

§ 166. The product of the co-sines of extremes disjunct, is equal to the product of radius and sine of the middle part.

§ 167. Every problem in right angled spherical trigonometry can be solved either by the one or the other of these two rules.

§ a. They have been put in the following mnemonic form :

“The *product* of radius and middle part's sine
 Equals *that* of the tangents of parts that combine ;
 Or, *that* of the co-sines of those that disjoin.”

§ 168. If the data and quæsitæ be opposite sides and angles, the problem proposed may be solved by the proportion (§ 144.) between the sines of opposite sides and angles.

§ 169. A B C represents a right angled spherical triangle upon a plane; B is the right angle, and b the hypotenuse.

§ a . The circular parts, commencing with c , and naming them in the order around to the right, in which they join; are c , a , $\cos. C$, $\cos. b$, and $\cos. A$.

CASE I.

§ 170. Given the hypotenuse (b) and a leg (c).

The hypotenuse $b = 74^\circ 40'$.

The leg $c = 60^\circ 14'$.

To find the other parts.

§ a . 1st. To find the other leg (a).

The three parts that, in this case, comprise the data and quæsitum of the problem, are the two legs (c , a), and the hypotenuse (b). The complement of b , (§ 163. § a .) is not adjacent to either of the other parts, (c , a .); therefore (§ 163.) it is the middle part, and c and a are extremes disjunct; and (§ 166.) $\cos. c \times \cos. a = \text{Sin. } b^\circ \times \text{Rad.}$;* then (§ 71.) $\cos. c : \text{Rad.} :: \text{sin. } b^\circ : \cos. a$.

$$c = 60^\circ 14'. \cos. \text{ar. co.} = 0.804108 (= \sec. c.)$$

$$\text{Radius} \qquad \qquad \qquad 10.$$

$$b = 74^\circ 40'. \cos. (= \text{sin. } b^\circ) = 9.423318$$

$$\text{Cos. } a = 9.726426 = 57^\circ 49'.$$

§ c . In looking in the tables for the degrees, etc., which correspond to the logarithmic co-sine, 9.726426, it will be seen that $122^\circ 11'$, the supplement of $57^\circ 49'$, also corresponds to it. Which of the two to take, is known (§ 141. § b .) by the affection of the two legs.

§ d . The sine, tangent, secant, etc., of an arc or angle, (§ 52. § d .) are the co-sine, co-tangent, co-secant, etc., of the complement of that arc, and (§ 104.) the sine, tangent, secant, etc., of the supplement of the same arc. Therefore,

§ e . Cor. The logarithmic value of any trigonometric function

* To obviate the necessity of writing *complement*, the circular parts of the hypotenuse and two angles will be denoted in the rest of the work by writing an ($^\circ$) after the letter which stands for any one of those parts. Thus, a° , C° , B° , stands for the complements of a , C , B .

corresponds to two arcs or angles; viz., an angle and its supplement. Thus, log. sine $9.611576 = 24^\circ 8'$, or $155^\circ 52'$.

§ f. There is generally some circumstance connected with the conditions of the problem, or triangle, under solution, which determines the affection of the required part, and thence the arc required; for every one of the sides and of the angles of a spherical triangle (§ 136. & § 137.), may be either greater or less than a right angle, or 90° .

§ g. To find the value of a . In this case A° is the middle part. It is between, and joins, the two other parts b° and c . Therefore (§ 162.) b° and c are extremes conjunct. And (§ 165.) $\text{rad.} \times \sin. A^\circ = \text{tang. } c \times \text{tang. } b^\circ$. Then (§ 71.), $\text{rad.} : \text{tang. } b^\circ :: \text{tang. } c : \sin. A^\circ$.

Radius	= 10.
$b = 74^\circ 40'$ co-tang.	= 9.438059 (= tang. b° , § 52. § d.)
$c = 60^\circ 14'$ tang.	<u>10.242655</u>

Sin. A° (= co-sin. A . (§ 52. § d.)) = 9.680714 = $61^\circ 21' 9''$.

§ h. $61^\circ 21' 9''$, and *not* its supplement, is known (§ 141. § b. & § d.) to be the required value of the angle A .

§ i. If the angle (C) opposite to (c) one of the given sides be required from the data of this case, the ratio (§ 144.) between the sines of opposite sides and angles, will determine the value of it, viz. : $\text{Sin. } b : \text{sin. } B$ (= (§ 62.) rad.) :: $\text{sin. } c : \text{sin. } C$.

§ j. Or the value of C may be determined by means (§ 166.) of the Catholic Proposition; c (§ 163.) is the middle part, and b° and C° are extremes disjunct; and (§ 166.) $\text{cos. } b^\circ \times \text{cos. } C^\circ = \text{sin. } c \times \text{rad.}$; wherefore (§ 71.) $\text{cos. } b^\circ : \text{rad.} :: \text{sin. } c : \text{cos. } C^\circ$; which is the proportion under § i., stated under different denominations, but the same ultimately; for the co-sine b° and $\text{cos. } C^\circ$ (§ 52. § d.) are the same as $\text{sin. } b$ and $\text{sin. } C$.

$b = 74^\circ 40'$ sin. ar. co.	= 0.015741 = co-sec. (§ 101. § b.)
Radius	= 10.
$c = 60^\circ 14'$ sine	<u>9.938547</u>

Sine $C = \underline{9.954288} = 64^\circ 10' 14''$ (§ 141. § d.)

CASE II.

§ 171. Given the hypotenuse (b)
and an angle (C),

$$b = 119^{\circ} 39'$$

$$C = 104^{\circ} 01'$$

To find the other parts.

§ a . 1st. To find the other angle (A).
The two angles (A, C) are adjacent to
the hypotenuse (b), which is therefore
(§ 162.) the middle part, and the two
angles (A, C) are extremes conjunct;
then (§ 170. § g .) $\text{tang. } C^{\circ} : \text{rad.} ::$
 $\text{sin. } b^{\circ} : \text{tang. } A^{\circ}$; and (§ 52. § d .) co-
 $\text{tang. } C : \text{rad.} :: \text{cos. } b : \text{cotang. } A$.

$$C = 104^{\circ} 01' \text{ co-tang. ar. co.} = 0.602691 = \text{tang. } (\S 100. \S a.)$$

$$\text{Radius} = 10.$$

$$b = 119^{\circ} 39' \text{ cos.} = 9.694342$$

$$\text{Co-tang. } A = 10.297033 = 26^{\circ} 46' 36''.$$

§ b . The value of A is known to be less than 90° (§ 141. § c),
because C is greater than a right angle.

§ c . 2d. To find a , which (§ 141. § d .) is also less than a right
angle. The three parts, a, C° , and b° , join in circular order; and
(§ 162. § c .) C° is the middle part, and b° and a are conjunct ex-
tremes. Then (§ 170. § g .) $\text{tang. } b^{\circ} : \text{rad.} :: \text{sin. } C^{\circ} : \text{tang. } a$; and
(§ 52. § d .) $\text{co-tang. } b : \text{rad.} :: \text{cos. } C : \text{tang. } a$.

$$b = 119^{\circ} 39' \text{ co-tang. ar. co.} = 0.244709 = \text{tang. } (\S 101. \S b.)$$

$$\text{Radius} = 10.$$

$$C = 104^{\circ} 01' \text{ cos.} = 9.384182$$

$$\text{Tang. } a = 9.628891 = 23^{\circ} 2' 58''.$$

§ d . 3d. To find c ; c (§ 141. § d .) is greater than a quadrant. The
method for finding the value of c in this case, is similar to that
(§ 170. § j .) of finding C , Case 1.

$$\text{Rad.} : \text{sin. } b :: \text{sin. } C : \text{sin. } c.$$

$$\text{Radius} = 10.$$

$$b = 119^{\circ} 39' \text{ sin.} = 9.939052$$

$$C = 104^{\circ} 01' \text{ sin.} = 9.986873$$

$$\text{Sin. } c = 9.925925 = 122^{\circ} 31' 18''.$$

CASE III.

§ 172. Given the two legs (a, c),
 $a=31^{\circ} 16'$
 $c=74^{\circ} 14'$

To find the other parts (A, C, b .)

§ a . 1st. To find the hypotenuse (b); it is less than a quadrant, because (§ 141. § b .) the legs are of the same affection. The three parts, a, b° , and c , do not join each other in the circular order; b° stands alone: then (§ 163. § a .) a and c are disjunct extremes, and b° is the middle part; and (§ 170. § a . & § XLIX. Alg.) radius :

cos. $c ::$ cos. $a : \sin. b^{\circ} =$ (§ 52. § d .) cos. b .

$$\begin{array}{r} \text{Radius} \qquad \qquad = 10. \\ c=74^{\circ} 14' \text{ cos.} = 9.434122 \\ a=31^{\circ} 16' \text{ cos.} = 9.931845 \end{array}$$

$$\text{Cos. } b = \underline{\underline{9.365967}} = 76^{\circ} 34' 12''.$$

§ b . 2d. To find an angle (C); it is less (§ 141. § d .) than 90° . The three parts C°, a, c , join in circular order; and (§ 162.) C° & c , are conjunct extremes, and a is the middle part: then (§ 165. & § 71.) tang. $c : \text{rad.} :: \sin. a : \text{tang. } C^{\circ} = \text{co-tang. } C$.

$$\begin{array}{r} c=74^{\circ} 14' \text{ tang. ar. co.} = 9.450777 = \text{co-tang.} \\ \text{Radius} \qquad \qquad \qquad = 10. \\ a=31^{\circ} 16' \text{ sine} \qquad \qquad = 9.715186 \end{array}$$

$$\text{Co-tang. } C = \underline{\underline{9.165963}} = 81^{\circ} 39' 47''.$$

§ c . 3d. To find the other angle (A); it is also less than 90° , and it is an extreme conjoined to a by c , which (c) is the middle part; then (§ b .) tang. $a : \text{rad.} :: \sin. c : \text{tang. } A^{\circ} = \text{co-tang. } A$.

$$\begin{array}{r} a=31^{\circ} 16' \text{ tang. ar. co.} = 0.216659 = \text{co-tang.} \text{ (§ 101. § } b \text{.)} \\ \text{Radius} \qquad \qquad \qquad = 10. \\ c=74^{\circ} 14' \text{ sin.} \qquad \qquad = 9.983345 \end{array}$$

$$\text{Co-tang. } A = \underline{\underline{10.200004}} = 32^{\circ} 15'.$$

CASE IV.

§ 173. Given the two angles (A, C),

$$A=31^{\circ} 56'$$

$$C=111^{\circ} 11'$$

To find the sides a , b , and c .

§ a. 1st. To find the hypotenuse (b); it is (§ 141. § c.) greater than a quadrant; it connects A° and C° in the circular order, which are conjunct extremes; and (§ 171. § a. § XLIX. Alg.)

$$\text{rad.} : \text{tang. } A^{\circ} :: \text{tang. } C^{\circ} : \text{sin. } b^{\circ}; \text{ or,}$$

$$\text{rad.} : \text{co-tang. } A :: \text{co-tang. } C : \text{cos. } b.$$

$$\text{Radius} = 10$$

$$A=31^{\circ} 56' \text{ co-tang.} = 10.205336$$

$$C=111^{\circ} 11' \text{ co-tang.} = 9.588316$$

$$\text{Cos. } b = 9.793652 = 128^{\circ} 26' 53''.$$

§ b. 2d. To find the leg c ; it and A° are extremes disjunct; and (§ 166. & § 71.)

$$\text{cos. } A^{\circ} : \text{rad.} :: \text{sin. } C^{\circ} : \text{cos. } c; \text{ or,}$$

$$\text{Sin. } A : \text{rad.} :: \text{cos. } C : \text{cos. } c.$$

$$A=31^{\circ} 56' \text{ sin. ar. co.} = 0.276600 = \text{co-sec.} (\S 101. \S b.)$$

$$\text{Radius} = 10.$$

$$C=111^{\circ} 11' \text{ cos.} = 9.557932$$

$$\text{Cos. } c = 9.834532 = 133^{\circ} 5' 32'' (\S 139.)$$

C and c (§ 141. § d.) are of the same affection.

§ c. 3d. To find the other leg a ; it is less than a quadrant, and a disjunct extreme; A° is the middle part, and (§ b.)

$$\text{cos. } C^{\circ} : \text{rad.} :: \text{sin. } A^{\circ} : \text{cos. } a; \text{ or,}$$

$$\text{Sin. } C : \text{rad.} :: \text{cos. } A : \text{cos. } a.$$

$$C=111^{\circ} 11' \text{ sin. ar. co.} = 0.030384 = \text{co-sec.} (\S 101. \S b.)$$

$$\text{Radius} = 10.$$

$$A=31^{\circ} 56' \text{ cos.} = 9.928736$$

$$\text{Cos. } a = 9.959120 = 24^{\circ} 28' 18''.$$

CASE V.

§ 174. Given an angle (C) and its
opposite leg (c),

$$c = 45^\circ 19'$$

$$C = 54^\circ 49'$$

To find the other parts (*a*, *b*, *A*).

§ *a*. This is called the "doubtful case," because there is nothing in the condition of any problem that falls under this case, which will determine the affection of the part whose value is sought.

§ *b*. 1st. To find the other leg (*a*); it is the middle part, connecting the conjunct extremes, C° and *c*; and (§ 172. § *b*.) $\text{rad.} : \text{tang. } C^\circ :: \text{tang. } c : \sin. a$, or,

$$\text{Rad.} : \text{co-tang. } C :: \text{tang. } c : \sin. a.$$

$$\text{Radius} \quad \quad \quad 10.$$

$$C = 54^\circ 49' \quad \text{co-tang.} = 9.848181$$

$$c = 45^\circ 19' \quad \text{tang.} = 10.004801$$

$$\text{Sin. } a = \frac{9.852982}{10} = 45^\circ 27' 54''.$$

§ *c*. 2d. To find the hypotenuse (*b*); it is a disjoined extreme, and is found (§ 170. § *j*.) $\cos. C^\circ : \text{rad.} :: \sin. c : \cos. b^\circ$; or,

$$\text{Sin. } C : \text{rad.} :: \sin. c : \sin. b.$$

$$C = 54^\circ 49' \quad \text{sin. ar. co.} = 0.087612 = \text{co-sec.} \quad (\S 101. \S b.)$$

$$c = 45^\circ 19' \quad \text{sin.} = 9.851872$$

$$\text{Radius} \quad \quad \quad = 10.$$

$$\text{Sin. } b = \frac{9.939484}{10} = 60^\circ 27' 2''.$$

§ *d*. 3d. To find the other angle (*A*); it is a disjunct extreme; and (§ 173. § *b*.) $\cos. c : \text{rad.} :: \sin. C^\circ : \cos. A^\circ$; or,

$$\text{Cos. } c : \text{rad.} :: \cos. C : \sin. A.$$

$$c = 45^\circ 19' \quad \text{cos. ar. co.} = 0.152929 = \text{sec.} \quad (\S 101. \S b.)$$

$$\text{Radius} \quad \quad \quad = 10.$$

$$C = 54^\circ 49' \quad \text{cos.} = 9.760569$$

$$\text{Sin. } A = \frac{9.913498}{10} = 55^\circ 1' 30''.$$

CASE VI.

§ 175. Given a leg (c) and its adjacent angle (A),

$$c = 35^\circ 15' 7''$$

$$A = 74^\circ 47'$$

To find the values of the other parts (b , C , a).

§ a . 1st. To find the value of the hypotenuse (b); it is (§ 141. § b . & § d .) less than a quadrant; and the problem is the converse of § g ., Case I, (§ 170.). Tang. c : rad. :: sin. A° : tang. b° ; or,

$$\text{Tang. } c : \text{rad.} :: \text{sin. } A : \text{co-tang. } b.$$

$$c = 35^\circ 15' 7'' \text{ tang. ar. co.} = 0.150715 = \text{cot. } (\S 101. \S b.)$$

$$\text{Radius} = 10.$$

$$A = 74^\circ 47' \text{ cos.} = 9.419080$$

$$\text{Co-tang. } b = 9.569795 = 69^\circ 37' 37''.$$

§ b . 2d. To find the value of the angle C . This is the converse of § b ., Case IV. (§ 173.), Radius : cos. A° :: cos. c : sin. C° ; or,

$$\text{Rad.} : \text{sin. } A :: \text{cos. } c : \text{cos. } C.$$

$$\text{Radius} = 10.$$

$$A = 74^\circ 47' \text{ sin.} = 9.984500$$

$$c = 35^\circ 15' 7'' \text{ cos.} = 9.912022$$

$$\text{Cos. } C = 9.896522 = 38^\circ 00' 7''.$$

§ c . 3d. To find the other leg a . The calculation for this is the converse of § c ., Case III., (§ 172.)

$$\text{Tang. } A^\circ : \text{rad.} :: \text{sin. } c : \text{tang. } a; \text{ and } \text{tang. } A^\circ =$$

$$\text{Co-tang. } A = 74^\circ 47' \text{ ar. co.} = 0.565421 = \text{tang. } (\S 101. \S b.)$$

$$\text{Radius} = 10.$$

$$c = 35^\circ 15' 7'' \text{ sin.} = 9.761305$$

$$\text{Tang. } a = 10.326726 = 64^\circ 46' (\S 141. \S d.)$$

§ 176. The rules which have been given for the solution of any problem that can occur in right angled spherical trigonometry, are good in theory; but instances may occur in practice, wherein they will not yield the most accurate result. This apparent defect arises from the trigonometric functions by which certain arcs, or angles, that enter into calculation, are denominated. For instance: If the required part be a very small arc or angle, and the result give its log.

co-sine, the solution is not a good one; because a small error in the log. cos. will produce a much larger one in the arc or angle. This arises from the different manner in which an arc and its sine increase.

§ a. By referring to a logarithmic table, even of six digits in the mantissæ, it will be observed that an arc of 89° 51' may increase 18', or to 90° 9', and that the value of its sine will only vary .000001.

§ b. The same thing is true of the co-sine of the complement of such an arc.

§ c. For these reasons, *the sine of an arc near 90°, or the cos. of one near 1', should not be used in trigonometrical calculation.*

§ 177. The value of sine and co-sine of such arcs may be substituted by their equivalents in other trigonometric functions.

§ 178. The principles from which such equivalents are obtained, are involved in § 75.

§ a. The elements of trigonometry are chiefly contained in the principles of § 43. and § 75.

§ 179. An equivalent for the sine, co-sine, etc., of any angle, may be found by means of the principles developed under § 75.

§ a. Let the proposed angle (C) be made an oblique angle in a right angled triangle (A B C); and from it, with its adjacent side (C B) as radius, describe the arc H B, and draw the sine (H p) of the angle (C) proposed; C p is its co-sine, A B its tangent, and C A its secant.

§ b. Now, instead of naming these sides by letters, denominate them by the trigonometric functions whose offices they fill; thus, calling H p, sin. C; C p, cos. C; A B, tang. C; and so on; we have (§ 75. and § 73.),

$$\text{Sin. C} : \text{cos. C} :: \text{tang. C} : \text{radius}; \text{ or, } \text{sin. C} = \frac{\text{Cos. C} \times \text{tang. C}}{\text{radius.}}$$

$$\text{§ c. Cos. C} : \text{sin. C} :: \text{rad.} : \text{tang. C}; \text{ or, } \text{cos. C} = \frac{\text{Sin. C} \times \text{rad.}}{\text{tang. C}}$$

§ d. Equivalents for other trigonometric functions may be found after a similar manner; and the same relations exist between the trigonometric functions of plane and spherical triangles. Therefore—

§ 180. The logarithmic sine of any angle is equal to its log. co-sine and tangent, minus radius, or 10. And—

§ 181. The log. cos. of any angle is equal to its log. sine and radius, minus the log. tang. of the same angle.

OBLIQUE SPHERICS.

0

OBLIQUE SPHERICS.

§ 182. In every oblique spherical triangle, there are *six parts*, any three of which constitute sufficient data (§ 145.) for determining the value of any of the remaining parts by means of trigonometrical calculation.

§ 183. Every problem in oblique spherical trigonometry is comprised in one of the six following cases; in which the data are,

1st, Two sides and angle opposite to one of them.

2d, Two angles and the side subtending either.

3d, Two angles and the side between them.

4th, Two sides and the angle they include.

5th, The three sides.

6th, The three angles.

§ 184. When any one of the four first cases, comprises the data of the problem, it may be solved by right angled trigonometrical operations; for this purpose the proposed triangle (§ 147. § a.) must be divided into two right angled triangles.

§ a. The perpendicular arc must be so drawn, that *two* of the given parts must be on the *same side* of it, and consequently, in one of the right angled triangles, into which this arc divides the triangle of the problem.

§ 185. The rules in right angled trigonometry, for determining *in species* an unknown side or angle, (i. e. whether it be greater or less than 90°), do not hold good in all cases in oblique trigonometry.

§ 186. The opposite sides and angles of oblique spherical triangles, are not necessarily of the same affection.

§ a. But if the greatest *side* be greater than a quadrant, it and its opposite angle are of the same affection.

§ 187. The converse of § 186. § a. does not hold good; for the sides (§ 136. § a.) of a spherical triangle may be indefinitely small, and the sum of the angles (§ 137.) being greater than two right angles, an obtuse angled spherical triangle may be formed of these indefinitely small sides; in which case an obtuse angle and its subtending side will be unlike.

§ 188. In most cases though, there are circumstances connected either with the condition of the problem, or of the triangle it involves, by which the species of the part required may be determined. Some of these circumstances are mentioned below.

§ 189. If an angle of a triangle be greater than 90° , an arc drawn from it, perpendicular to the subtending side, will fall *within* such triangle.

§ a. If the angles adjacent to the base, be of the same affection, the perpendicular falls upon it, also within the triangle.

§ 190. If all the angles of a triangle be not of the same affection, and a perpendicular arc be drawn from one of the angles which is less than 90° upon the subtending side, it will fall *without* the triangle.

§ 191. An opposite side and angle of a spherical triangle cannot be unlike, unless the sine of this side be greater than the sines of the other sides.

§ *a*. The sine of the angle opposite to such a side is also greater than the sines of the two other angles.

§ *b*. In an isosceles triangle, each side and its opposite angle are alike.

§ 192. If an obtuse side be opposite to an acute angle in any triangle, the two other sides are unlike; and (§ 191.) they and their opposite angles are of the same affection; consequently, the two angles are unlike.

§ *a*. If an obtuse angle subtend an acute side, the other sides and angles are all alike.

§ 193. Whether the perpendicular fall within or without the triangle, the less segment of the base is next to that angle which, of the two adjacent to the base, is the nearer 90° .

§ *a*. When the perpendicular falls within the triangle, the sum of the segments equals the base.

§ *b*. And when it falls without the triangle, the base equals the difference of the segments.

§ 194. If a side and its subtending angle be each less than 90° , a smaller side and its opposite angle, of the same triangle, must be (§ 139.) of the same affection.

§ 195. If the sum of two angles of a triangle be less than 90° , the third angle (§ 137.) is greater than a right angle.

§ 196. By writing co-tang. for the arithmetical complement (§ 101. § *b*.) of the tangent; sec. for the arithmetical complement of cos.; cosec. for the arithmetical complement of sine, etc., greater simplicity and uniformity of calculation will be effected.

§ *a*. The learner will have observed by the reference (§ 101. § *b*.) appended to the arithmetical complement of sines, etc., in some of the calculations in right angled spherical trigonometry, that by taking from the tables the cosec. of an arc, he obtains at once the arithmetical complement of the logarithmic sine of the same arc. So, co-tang. for arithmetical complement of the tangent, etc.

CASE I.

§ 197. Given two sides (*b* & *c*) and an angle (*C*) opposite to one of them,

$$b = 21^\circ 17'$$

$$c = 74^\circ 14'$$

$$C = 69^\circ 10'$$

To find the other parts (*A*, *B* and *a*) by right angular operations.

§ *a*. If the third side (*a*) or its oppo-

site angle (A) be computed, the two other remaining parts are determinable by means of the ratio (§ 144.) between the sines of opposite sides and angles.

§ b. In order that two (*b* & *C*) of the given parts, may be on the same side (§ 184. § a.) of the perpendicular *A p*, it is drawn from *A*, upon its opposite side *a*, so as to divide the triangle of the problem into two right angled triangles *A p C* and *A p B*; the former of which contains two of the given parts (*C* & *b*).

§ c. *C* & *B* are less than 90° (§ 184.); therefore (§ 141. § b.) *C p* & *A p* are each less than 90°; the perpendicular upon the side (*a*) adjacent to *C* & *B* (§ 189. § a.) falls within the triangle; and makes the sum of the segments of the angle *A*, equal to *A*.

§ d. The distance (*C p*) of the given angle (*C*) from the intersecting point (*p*) of the perpendicular and the base, is called auxiliary *a'*.

§ e. To compute the value of the auxiliary arc *a'*.

The method of doing it, is shown under Case II. (§ 171. § c.).

$$\text{Tang. } a' = \frac{\cos. C}{\cot. b} = (\S 196.) \text{ tang. } b \cos. C.$$

$$\begin{aligned} \S f. \quad b &= 21^\circ 17'. & \text{Tang.} &= 9.590562 \\ C &= 69^\circ 10'. & \text{Cos.} &= 9.551024 \end{aligned}$$

$$\text{Tang. auxl. } a' = 9.141586 = 7^\circ 52' 16''^*$$

§ g. The value of *B* is calculated from the ratio (§ 144.) between the sines of sides and of angles. $\text{Sin. } c : \text{sin. } C :: \text{sin. } b : \text{sin. } B$; $\text{sin. } c \text{ ar. co. } (\S 196.) = \text{cosec. } c$.

$$\begin{aligned} \S h. \quad c &= 74^\circ 14' & \text{cosec.} &= 0.016655 \\ C &= 69^\circ 10' & \text{sin.} &= 9.970635 \\ b &= 21^\circ 17' & \text{sin.} &= 9.559883 \end{aligned}$$

$$\text{Sin. } B = 9.547173 = 20^\circ 38' 27''$$

§ i. Now, in the other right angled triangle *A p B*, the value both of *c* and of *B* is known, and the other segment (*p B*) of the base can be determined; for (§ e.) $\text{tang. } B p = \cos. B \text{ tang. } c$.

$$\begin{aligned} \S j. \quad c &= 74^\circ 14' & \text{tang.} &= 0.549223 \\ B &= 20^\circ 38' 27'' & \text{cos.} &= 9.971187 \end{aligned}$$

$$\text{Tang. } B p = 0.520410 = 73^\circ 12' 39''$$

* Rad. (§ 98. § b.), being always equal to 1 or to 10 in logarithmic calculations, is not written down in these formulæ; its value is brought into account by applying it to the log. index of the result, as in the case above. By omitting rad. the formulæ for calculation are rendered more compact and convenient. The proper value will always be given rad. in calculation, by having the log. index of the result to consist only of one figure, as in the case above, where radius is taken into the account by simply writing 9 instead of 19 for the log. index of auxl. *a'*.

§ k. The perpendicular falling within the triangle, makes the *sum* of the segments (§ 193. § a.) equal to the base *a*; therefore (§ f. & § j.) $a = 81^\circ 5' 55''$.

§ l. To find the value of A.

Sin. <i>c</i> :	sin. C :	::	sin. <i>a</i> :	sin. A.
<i>c</i> = 74° 14'	cos. = 0.016655			
C = 69° 10'	sin. = 9.970635			
<i>a</i> = 81° 5' 55''	sin. = 9.994738			

$$\text{Sin. A} = 9.982028 = 106^\circ 22' 12''; \text{ A is greater}$$

(§ 195.) than 90°.

§ m. The value of A may also be determined by the Catholic Proposition; for (§ 171. § a.) $\cotang. C A p = \frac{\cos. b}{\cot. C} = (\S 196.) \cos. b \text{ tang. C}$. Also $\text{co-tang. B A } p = \cos. c \text{ tang B}$.

§ n. $B A p + C A p = A$, according as the perpendicular arc A p falls within or without the triangle.

§ o. C = 69° 10'	tang. = 0.419611
<i>b</i> = 21° 17'	cos. = 9.969321

$$\text{Co-tang. C A } p = 0.388932 = 22^\circ 12' 51''$$

B = 20° 38' 27''	tang. = 9.575983
<i>c</i> = 74° 14'	cos. = 9.434122

$$\text{Co-tang. B A } p = 9.010105 = 84^\circ 9' 21''$$

$$B A p + C A p (\S c.) = A \quad 106^\circ 22' 12''$$

§ p. The process of solution by such methods of calculation as the above, is circuitous. But cases sometimes occur when they may be used with advantage. And in order that the process, by which the required result is obtained from calculations conducted upon the principles of right angled spherical trigonometry, may be made familiar to the learner, the calculations are carried out.

§ q. By analysis and the use of a little artifice, rules are deduced, and formula constructed, for obtaining the same result from the application of the same principles to calculation, but by less tedious operations. The *auxiliary arcs* and *angles* used in such methods, are derived from the principles of the Catholic Proposition; and the methods themselves are nothing more than right angled spherical calculations, rendered less circuitous in execution by previous combinations, eliminations, and substitutions of the parts that are contained in the two right angled triangles, into which the oblique one of the problem is divided.

§ r. To find the value of A by the help of auxiliaries. Let the angle B A p be called auxiliary A''; and let auxiliary A', be the angle (C A p) which is in the right angled triangle in which two (b, C,) of the given parts of the primitive triangle are contained.

§ s. According to § m. co-tang. $A' = \cos. b \text{ tang. } C$.

§ t. Now, (§ 165. & § XLV. Alg.); $\frac{\text{Tang. } A p}{\text{rad.}}$

$$\frac{\text{Cos. } A'}{\text{cot. } b}; \text{ also } \frac{\text{Tang. } A p}{\text{rad.}} = \frac{\text{Cos. } A''}{\text{cot. } c}; \text{ wherefore } \frac{\text{Cos. } A'}{\text{cot. } c} =$$

$$\frac{\text{Cos. } A'}{\text{cot. } b}; \text{ and by transposition, } \text{Cos. } A'' = \frac{\text{Cos. } A' \text{ Cot. } c}{\text{cot. } b}$$

& (§ 101. § b.) $\frac{\text{Cos. } A' \text{ Cot. } c}{\text{cot. } b} = \text{Cos. } A' \text{ Cot. } c \text{ tang. } b$. Therefore,

Cos. auxiliary $A'' = \cos. A' \text{ cot. } c \text{ tang. } b$. Whence the general rule for finding the value of (A) the angle opposite to the unknown side.

§ u. The product (§ s.) of tang. of the given angle, and cos. of the given side that is adjacent to it, is co-tang. of auxiliary A' . And,

§ v. The product of tang. of the same side, and co-tang. of the other given side, multiplied by cos. of auxl. A' (§ t.), is cos. of the other auxiliary A'' . And the sum (§ 193. § a.), or difference (§ 193. § b.), of the two auxiliaries, gives the required angle.

§ w.	$c = 74^\circ 14'$
$b = 21^\circ 17'$	$\text{cot.} = 9.450777$
$\text{cos.} = 9.969321$	$\text{tang.} = 9.590562$
$C = 69^\circ 10'$	$\text{tang.} = 0.419611$

$$\text{Cot. } A' = 9.388932 = 22^\circ 12' 51'' \quad - \quad \text{cos.} = 9.966506$$

$$84^\circ 9' 21'' \quad - \quad \text{Cos. } A'' = 9.007845$$

$$A = 106^\circ 22' 12'' \text{ (§ o.)}$$

§ x. The formula for the calculation (§ w.) is arranged in the most convenient order for operation. The value of auxl. A' is evolved during the process of finding that of the other A'' ; and the log. tang. and cos. of b , are taken out at one opening of the tables; so, also is the value of A' and its cos. System and method in calculation should by no means be neglected. They promote accuracy and facilitate practice. It is therefore the business of every calculator to introduce system in his operations. The habit of arranging the several quantities in the most convenient order for calculation, contributes to accuracy, and makes verification more ready.

§ y. To find the value of a , by the help of auxiliaries. Call the segment $C p$, auxl. a' , and the segment $B p$, auxl. a'' .

§ z. From a train of reasoning analogous to that under § m., it is shown that, tang. auxl. $a' = \text{tang. } b \text{ cos. } C$.

$$\text{§ z a. Also (166. & § XLV. Alg.) } \frac{\text{Rad.}}{\text{cos. } A p} = \frac{\text{Cos. } a'}{\text{cos. } b}; \text{ and}$$

$$\frac{\text{Rad.}}{\text{cos. } A p} = \frac{\text{Cos. } a''}{\text{cos. } c}; \text{ therefore } \frac{\text{Cos. } a''}{\text{cos. } c} = \frac{\text{Cos. } a'}{\text{cos. } b}; \text{ and by transpo-}$$

sition $\cos. a' = \frac{\text{Cos. } a \cos. c}{\cos. b} = (\S 101. \S b.) \cos. a' \cos. c \sec. b$;
 then $a' \overset{+}{\infty} a'' (\S c. \& \S n.) = a$. Whence the general rule for finding
 the third side.

§ z b. The product of cos. of the given angle and tang. of its ad-
 jacent side, is (§ z.) tang. of auxl. a' . And,

§ z c. Sec. of the same side, multiplied by the *product* of cos. of
 the other side and cos. of auxl. a' (§ z a.), is cos. of the other
 auxl. a'' .

§ z d. If the two angles adjacent to the base, be each less than
 90° , the perpendicular falls within the triangle, and (§ 193. § a.) the
sum of the auxiliaries is the required part.

§ z e. But if these two angles be unlike, the perpendicular falls
 without the triangle; and then (§ 193. § b.) the *difference* of the
 auxiliaries is the required part.

§ z f.
 $b = 21^\circ 17'$ tang. = 0.590562 $c = 74^\circ 14'$ cos. = 0.434123
 $C = 69^\circ 10'$ cos. = 0.551024 - - sec. = 0.030079

Tang. $a' = 0.141586 = 7^\circ 53' 16''$ - cos. = 0.995872

73° 12' 39'' - Cos. $a'' = 0.499979$

$a = 81^\circ 5' 55''$ (§ z d.)

§ z g. The value of the third side (a), or of its opposite angle
 (A), may also be determined by another method; but in this, the
 value of the other unknown angle (B) is necessary.

§ z h. To determine the third side (a),

Is to the cos. of $\frac{1}{2}$ the difference of the two angles, (B, C);

As to the cos. of $\frac{1}{2}$ their sum;

As tang. of $\frac{1}{2}$ the sum of the two sides (b, c);

Is to tang. of $\frac{1}{2}$ the required side.

§ z i. $\frac{1}{2} (C \infty B) = 24^\circ 15' 46''$ sec. = 0.040162

$\frac{1}{2} (C + B) = 44^\circ 54' 13''$ cos. = 0.850215

$\frac{1}{2} (b + c) = 47^\circ 45' 30''$ tang. = 0.041880

Tang. $\frac{1}{2} a = 0.932257 = 40^\circ 32' 58''$

2

$a = 81^\circ 5' 56''$

§ z j. To find the value of A by a similar method.

Is to the cos. of $\frac{1}{2}$ the difference of the two sides (b, c);

As to the cos. of $\frac{1}{2}$ their sum;

As tang. of $\frac{1}{2}$ the sum of the two angles (A, B);

Is to co-tang. of $\frac{1}{2}$ the angle required.

$$\begin{aligned} \S z k. \frac{1}{2} (c \pm b) &= 26^\circ 28' 30'' \text{ sec.} = 0.048114 \\ \frac{1}{2} (c + b) &= 47^\circ 45' 30'' \text{ cos.} = 9.827537 \\ \frac{1}{2} (C + B) &= 44^\circ 54' 13'' \text{ tang.} = 9.998538 \end{aligned}$$

$$\text{Co-tang. } \frac{1}{2} A = 9.874189 = 53^\circ 11' 7''$$

$$\begin{array}{r} 2 \\ \hline A = 106^\circ 22' 14'' \\ \hline \end{array}$$

These two last methods are the most common in practice.

CASE II.

§ 198. Given two angles and the side that subtends one of them,

$$\begin{aligned} B &= 29^\circ 16' \\ C &= 150^\circ 51' 50'' \\ b &= 74^\circ 46' \end{aligned}$$

To find the value of each of the other parts (A, c & a.)

§ a. The value of c (§ 144.) is determinable by a direct calculation; Sin. B : sin. c :: sin. C :

$$\begin{aligned} B &= 29^\circ 16' & \text{co-sec.} &= 0.810802 \\ b &= 74^\circ 46' & \text{sin.} &= 9.984466 \\ C &= 150^\circ 51' 50'' & \text{sin.} &= 9.687427 \end{aligned}$$

$$\text{Sin. } c = 9.982695 = 106^\circ 4' 2''$$

§ b. Suppose the perpendicular (A p) from A, upon the side opposite to A, to fall without the triangle. Then the two known parts in the right angled triangle A p C, are b, and (§ 192.) the supplement of C. The unknown parts of the proposed oblique triangle may be computed by right angled trigonometric operations.

§ c. In the triangle A p C, (§ 197. § e.) tang. C p = cos. C tang. b. Also in the triangle p A B, tang. p B = cos. B tang. c. Then (§ 193. § b.) C p ∝ p B = a.

§ d. The value of A also, may be determined by rules of right angled trigonometry.

§ e. When the perpendicular falls without the triangle, the difference of the two auxiliary angles B A p, and C A p, is the angle A.

P

§ f. But if it falls within the triangle, $B A p + C A p = A$, (§ 197. § n.)

§ g. Co-tang. $p A C = \cos. b \text{ tang. } C$; and co-tang. $B A p = \cos. c \text{ tang. } B$ (§ 197. § m.). Then (§ e.) $A = B A p + C A p$.

§ h. $C = 150^\circ 51' 50''$ $\cos. = 9.941246$ (§ c.)

$b = 74^\circ 46'$ $\text{tang.} = 0.564922$

$\text{Tang. } C p = \frac{0.506168}{0.564922} = 72^\circ 41' 3''$

$B = 29^\circ 16'$ $\cos. = 9.940693$

$c = 106^\circ 4' 2''$ $\text{tang.} = 0.540585$

$\text{Tang. } p B = \frac{0.481278}{0.540585} = 106^\circ 16' 15''$

Now (§ c.) $p B - C p = a = 35^\circ 35' 12''$

§ i. $C = 150^\circ 51' 50''$ $\text{tang.} = 9.746181$ (§ g.)

$b = 74^\circ 46'$ $\cos. = 9.419544$

$\text{Co-tang. } p A C = \frac{9.165725}{9.419544} = 81^\circ 40' 4''$

$c = 106^\circ 4' 2''$ $\cos. = 9.442111$

$B = 29^\circ 16'$ $\text{tang.} = 9.748505$

$\text{Co-tang. } B A p = \frac{9.190616}{9.748505} = 98^\circ 49' 0''$

Now (§ e.) $B A p - p A C = A = 17^\circ 8' 56''$

§ j. To determine the third angle (A) by the help of auxiliaries. The angle $p A C$ is auxiliary A' ; and the angle $B A p$ is auxiliary A'' .

§ k. Co-tang. $A' = \cos. b \text{ tang. } C$ (§ g.).

§ l. And (§ 166. and § XLV. Alg.) $\frac{\text{Rad.}}{\cos. A p} = \frac{\text{Sin. } A'}{\cos. C}$; also

$\frac{\text{Rad.}}{\cos. A p} = \frac{\text{Sin. } A''}{\cos. B}$; therefore $\frac{\text{Sin. } A''}{\cos. B} = \frac{\text{Sin. } A'}{\cos. C}$; and by trans-

position, $\text{sin. } A'' = \frac{\text{Sin. } A' \cos. B}{\cos. C} = (\text{\S 101. } \text{\S } b.) = \text{sin. } A' \cos. B$

sec. C . Whence the general rule for finding the third angle.

§ m. The product of $\cos.$ of the given side, and tang. of its adjacent angle, (§ k.) is co-tang. of auxl. A' . And,

§ n. The product of sec. of the same angle, and sin. of auxl. A' , multiplied by $\cos.$ of the other angle, (§ b.) is sin. of auxl. A'' . And (§ 197. § n.) $A' + A''$ is the required angle.

$$\begin{array}{l} \S o. \\ C=150^{\circ} 51' 50'' \text{ tang.} = 9.746181 \\ b=74^{\circ} 40' \text{ cos.} = 9.419544 \end{array} \qquad \begin{array}{l} B=29^{\circ} 16' \text{ cos.} = 9.940693 \\ \text{sec.} = 0.058754 \end{array}$$

$$\text{Cot. } A' = 9.165725 = 81^{\circ} 40' 4'' \qquad \text{sin.} = 9.995391$$

$$98^{\circ} 49' \qquad \text{Sin. } A'' = 9.994838$$

$$A = 17^{\circ} 8' 56'' (\S e.)$$

$\S p.$ To determine the value of the side (a) opposite to the unknown angle with the help of auxiliaries. Let the segment $p C$ be auxiliary a' ; and the other segment $p B$, be auxiliary a'' ,

$\S q.$ Tang. a' ($\S c.$) = cos. C tang. b .

$\S r.$ And by a process of reasoning similar to that under Case I, ($\S 197. \S z a.$), it is shown that $\text{sin. } a'' = \text{sin. } a' \text{ tang. } C \text{ co-tang. } B$;

for ($\S 165.$) $\frac{\text{Tang. } A p}{\text{rad.}} = \frac{\text{Sin. } a'}{\text{cot. } C}$; also $\frac{\text{Tang. } A p}{\text{rad.}} = \frac{\text{Sin. } A''}{\text{cot. } B}$;

therefore, $\frac{\text{Sin. } a''}{\text{cot. } B} = \frac{\text{Sin. } a'}{\text{cot. } C}$; and by transposition, $\text{sin. } a'' =$

$\frac{\text{Sin. } A' \text{ cot. } B}{\text{cot. } C} = \text{sin. } a' \text{ cot. } B \text{ tang. } C.$ Whence the general rule

for finding the value of the side that subtends the unknown angle.

$\S s.$ The product of tang. the given side, and cos. its adjacent angle ($\S q.$) is tang. of auxl. a' . And,

$\S t.$ Tang. the same angle multiplied by the product of co-tang. the other angle, and sin. the auxl. a' , is sin. the other auxiliary a'' .

$$\begin{array}{l} \S u. \\ C=150^{\circ} 51' 50'' \text{ cos.} = 9.941246 \\ b=74^{\circ} 46' \text{ tan.} = 0.564922 \end{array} \qquad \begin{array}{l} B=29^{\circ} 16' \text{ cot.} = 0.251495 \\ \text{tang.} = 9.746181 \end{array}$$

$$\text{Tang. } a' = 0.506168 = 72^{\circ} 41' 3'' \qquad \text{sin.} = 9.979857$$

$$108^{\circ} 16' 15'' \text{ Sin. } a'' = 9.977533$$

$$a = 35^{\circ} 35' 12''$$

CASE III.

§ 199. Given two angles, and the side between them,

$$A=19^{\circ} 41'$$

$$B=134^{\circ} 17'$$

$$c=36^{\circ} 19'$$

To find the value of the other parts (a , b , & C .)

§ a . The perpendicular (Ap) being so drawn that the two given parts B , c , may

be on the same side of it, falls without the triangle proposed; and (§ 198. § e .) the auxiliary angle $BAp+A$, equals the auxiliary angle CAp . Also the difference of the auxiliary arcs pB & pC (§ 193. § b .) is the side a .

§ b . If any one of the unknown parts be determined, the two others may be found from the proportion between the sines of opposite sides and angles.

§ c . To determine the value of C by the rules of right angled trigonometry.

§ d . In the right angled triangle BpA , (§ 165. & § 197. § m .) $\text{co-tang. } BAp = \cos. c \text{ tang. } B$. Also, (§ 166.) $\sin. Ap = \sin. B \sin. c$. And $BAp+A = CAp$.

§ e . Then in the right angled triangle CpA , the parts CAp & Ap are known, and (§ 166.) $\cos. C = \sin. CAp \cos. Ap$.

$$\text{§ } f. c=36^{\circ} 19' \cos. = 0.906204$$

$$B=134^{\circ} 17' \text{ tang.} = 0.010866$$

$$\text{Co-tang. } BAp = 0.917079 = 50^{\circ} 26' 15''$$

$$c \sin. = 0.772503$$

$$B \sin. = 0.854850$$

$$\text{Sin. } Ap = 0.627353 = 25^{\circ} 5' 12''$$

$$BAp+A = CAp = 70^{\circ} 7' 15'' \text{ (§ } a.)$$

$$\text{§ } g. CAp = 70^{\circ} 7' 15'' \sin. = 0.973318$$

$$Ap = 25^{\circ} 5' 12'' \cos. = 0.956969$$

$$\text{Cos. } C = 0.930267 = 31^{\circ} 36' 10''$$

§ h . To find the value of the third angle (C), with the help of auxiliaries. The angle BAp is auxiliary A' . $\text{Co-tang. } A' \text{ (§ } d.) = \cos. c \text{ tang. } B$.

§ i. And (§ 198. § l.) $\frac{\text{Cos. } A p}{\text{rad.}} = \frac{\text{Cos. } B}{\text{Sin. } A'}$; also $\frac{\text{Cos. } A p}{\text{rad.}} = \frac{\text{Cos. } C}{\text{sin. } (A + A')}$; therefore $\frac{\text{Cos. } C}{\text{sin. } (A + A')} = \frac{\text{Cos. } B}{\text{sin. } A'}$; and by transposition, $\text{Cos. } C = \frac{\text{Cos. } B \text{ sin. } (A + A')}{\text{sin. } A'} = \text{cos. } B \text{ sin. } (A + A') \text{ co-sec. } A'$.

§ j. $\text{Cos. } C = \text{cos. } B \text{ co-sec. } A' \text{ sin. } (A + A')$ when $A p$ falls without the triangle. And,

§ k. $\text{Cos. } C = \text{cos. } B \text{ co-sec. } A' \text{ sin. } (A - A')$ when $A p$ falls within it. Whence the rule.

§ l. The product of cos. the given side, and tang. of either angle (§ h.), is co-tang. of auxl. A' . And, (§ i.),

§ m. Cos. of the same angle, multiplied by the product of co-sec. of auxl. A' and sine of the sum (§ j.), or difference (§ k.) of auxl. A' and the other angle, is cos. of the required angle.

§ n.

$$c = 36^\circ 19' \text{ cos.} = 9.906204$$

$$B = 184^\circ 17' \text{ tang.} = 0.010866$$

$$\text{cos.} = 9.843984$$

$$\text{Cot. } A' = 9.917070 = 50^\circ 26' 15'' \quad \text{cosec.} = 0.112985$$

$$(A + A') = 70^\circ 7' 15'' \text{ sin.} = 9.978818$$

$$31^\circ 36' 10'' \text{ Cos. } C = 9.930287$$

To find the value of the two sides (a and b) with the help of auxiliaries.

§ o. According to a train of reasoning similar to that shown under Case I, (§ 197. § t.) $\text{cot. } b = \text{cot. } c \text{ cos. } (A + A') \text{ sec. } A'$; for

$$\frac{\text{Rad.}}{\text{Cot. } b} = \frac{\text{Cot. } c}{\text{cos. } A'}; \text{ also } \frac{\text{Rad.}}{\text{Cot. } b} = \frac{\text{Cot. } c \text{ cos. } (A + A')}{\text{Cot. } b}; \text{ then}$$

$$\frac{\text{Cot. } c \text{ cos. } (A + A')}{\text{Cot. } b} = \text{cos. } A'; \text{ and by transposition, } \text{cot. } b =$$

$$\frac{\text{Cot. } c \text{ cos. } (A + A')}{\text{cos. } A'} = \text{cot. } c \text{ cos. } (A + A') \text{ sec. } A'.$$

§ p. By drawing the perpendicular from B upon its opposite side, and calling the angle $A B b$ auxiliary B' , we obtain by a similar process of reasoning. $\text{Cot. } a = \text{cot. } c \text{ cos. } (B + B') \text{ sec. } B'$.

§ q. $\text{Cot. } B' = \text{cos. } c \text{ tang. } A$. Whence the rule for finding the value of either unknown side.

§ r. The product of cos. the given side and tang. of the angle (§ h. & § q.) opposite to the required side, is co-tang. of the required auxiliary which call A' . And (§ o. & § p.),

§ s. The product of cot. the given side and sec. of this auxl. A' ,

multiplied by cos. of the sum, or difference of A' and the angle adjacent to the required side, is co-tang. of the required side.

§ *t.* To find the value of *b* by this rule.

$$B = 134^\circ 17' \text{ tang.} = 0.010866$$

$$c = 36^\circ 19' \text{ cos.} = 9.906204 \quad - \quad - \quad - \quad \text{cot.} = 0.133700$$

$$\text{Cot. } A' = 9.917070 = 50^\circ 26' 15'' \quad - \quad \text{sec.} = 0.195916$$

$$(A + A') = 70^\circ 7' 15'' \text{ cos.} = 9.531528$$

$$54^\circ 0' 27'' \text{ Cot. } b = 9.861144$$

§ *u.* To find the value of *a* by the same rule.

$$A = 19^\circ 41' \text{ tang.} = 9.553548$$

$$c = 36^\circ 19' \text{ cos.} = 9.906204 \quad - \quad - \quad - \quad \text{cot.} = 0.133700$$

$$\text{Cot. } A' = 9.459752 = 73^\circ 55' 15'' \quad - \quad \text{sec.} = 0.557576$$

$$(B - A') = 60^\circ 21' 45'' \text{ cos.} = 9.694175$$

$$22^\circ 22' 32'' \text{ Cot. } a = 0.385451$$

§ *v.* A triangle that has a side or an angle greater than 180° must never be used in the solution of trigonometrical problems.

§ *w.* Therefore in the solution of all cases (§ *u.*) where the sum, or difference of an auxiliary, and an arc or angle, is to be brought into calculation, if the *sum* would exceed 180° , the *difference* is the proper quantity to be used.

§ *x.* The two unknown sides may also be determined by a method of calculation differing from that above, but depending on principles analogous to those under § 77. for plane triangles. This method is the most common in practice.

§ *y.* The sine of $\frac{1}{2}$ the *sum* of the two given angles (A, B);
Is to the sine of $\frac{1}{2}$ their *difference*;
As the tang. of $\frac{1}{2}$ the given side (c);
Is to the tang. of $\frac{1}{2}$ the *difference* of the two required sides (a, b). And,

§ *z.* Cos. of the *same* $\frac{1}{2}$ *sum*;
Is to the cos. of the *same* $\frac{1}{2}$ *difference*;
As the tang. of $\frac{1}{2}$ the given side;
Is to the tang. of $\frac{1}{2}$ the *sum* of the two required sides (a, b.)

$$\begin{aligned} \S z a. \quad \frac{1}{2} (A+B) &= 76^\circ 59' \text{ co-sec.} = 0.011305 \\ \frac{1}{2} (A-B) &= 57^\circ 18' \text{ sin.} = 9.925060 \\ \frac{1}{2} c &= 18^\circ 9' 30'' \text{ tang.} = 9.515844 \end{aligned}$$

$$\text{Tang. } \frac{1}{2} (a \times b) = 9.452209 = 15^\circ 48' 58''$$

$$\begin{aligned} \frac{1}{2} (A+B) \text{ sec.} &= 0.647365 \\ \frac{1}{2} (A-B) \text{ cos.} &= 9.732587 \\ \frac{1}{2} c \text{ - tang.} &= 9.515844 \end{aligned}$$

$$\text{Tang. } \frac{1}{2} (a+b) = 9.895796 = 38^\circ 11' 29''$$

§ z b. The greater side (*b*) is opposite (§ 139.) to the greater angle; and (§ 77. § g.) $38^\circ 11' 29'' + 15^\circ 48' 58'' = 54^\circ 00' 27''$ or *b*; and $a = (38^\circ 11' 29'' - 15^\circ 48' 58'') = 22^\circ 22' 31''$.

§ z c. To determine the value of the third angle (*C*) with the help of an auxiliary arc *a'*.

§ z d. The sine of $\frac{1}{2}$ the sum } of the two given angles
 Is to $\frac{1}{2}$ the sum of the sines } (*A* & *B*);
 As the sine of $\frac{1}{2}$ the given side (*c*);
 Is to the sine of auxl. *a'*. Then,

§ z e. The product of cos. of auxl. *a'* and sine of $\frac{1}{2}$ the sum of the two given angles, is cos. of $\frac{1}{2}$ the third angle (*C*).

$$\begin{aligned} \S z f. \quad B &= 134^\circ 17' \text{ sin.} = 9.854850 \\ A &= 19^\circ 41' \text{ sin.} = 9.527400 \end{aligned}$$

$$2) 19.382250$$

$$9.691125 = \frac{1}{2} \text{ sum of the sines of the two given angles.}$$

$$\begin{aligned} \frac{1}{2} c = 18^\circ 9' 30'' \text{ sin.} &= 9.493659 \\ \frac{1}{2} (A+B) = 76^\circ 59' \text{ co-sec.} &= 0.011305 \quad - \quad \text{sin.} = 9.988695 \end{aligned}$$

$$\text{Sin. auxl. } a' = 9.196089 = 9^\circ 2' 12'' \text{ cos.} = 9.994576$$

$$15^\circ 48' 5'' \text{ Cos. } \frac{1}{2} C = 9.983271$$

2

$$C = 31^\circ 36' 10''$$

CASE IV.

§ 200. Given two sides and the angle they include,

$$\begin{aligned} a &= 109^\circ 30' \\ b &= 60^\circ 00' \\ C &= 27^\circ 08' \end{aligned}$$

To find the other parts (A, B, c). This is the converse of Case III., for we have to find here what is there given.

§ a. If the perpendicular A p fall within the triangle, the sum of the segments (C p + p B) is equal to a; and the sum of the auxiliary angles, C A p + p A B = A.

§ b. Any one of the unknown parts of the triangle proposed, being found, the two others are determinable from the relations (§ 144.) of sides to their opposite angles.

§ c. To find B, by the Catholic Proposition. By Case II.,

$$(\S 171. \S c.) \text{ tang. } C p = \frac{\text{Cos. } C}{\text{Cot. } b} = (\S 101. \S b.) \cos. C \text{ tang. } b; \text{ also}$$

(§ 171. § d.) $\sin. A p = \sin. b \sin. C$. Then (§ a.) $a - C p = p B$; and the value of A p, and of B p, in the triangle A p B, being known, that of B (§ 155.) is determinable; $\cotang. B = (\S 172. \S b.) = \frac{\text{Sin. } p B}{\text{Tang. } A p} = \sin. p B \cotang. A p$.

$$\begin{aligned} \S d. C = 27^\circ 8' \quad \cos. &= 9.949494 \\ b = 60^\circ 0' \quad \text{tang.} &= 0.238561 \end{aligned}$$

$$\text{Tang. } C p = \frac{0.168055}{0.238561} = 57^\circ 2' 4''$$

$$\begin{aligned} C \sin. &= 9.658531 \\ b \sin. &= 9.937531 \end{aligned}$$

$$\text{Sin. } A p = \frac{9.596062}{9.937531} = 23^\circ 14' 8''$$

$$109^\circ 30' - 57^\circ 2' 4'' (\S a.) = p B = 52^\circ 27' 56''$$

$\S e.$ p $B=52^{\circ} 27' 58''$ $\text{Sin.} = 9.899267$
 A $p=29^{\circ} 14' 8''$ $\text{Cotang.} = 0.367204$

Cotang. B=10.266471=28^{\circ} 25' 54''

$\S f.$ To find the value of each of the unknown angles (A, B), with the help of an auxiliary arc (a'). A perpendicular drawn from either of the unknown angles (A, B) fulfils the conditions of $\S a.$ (§ 184.); suppose the perpendicular drawn from B to the fall without the triangle.

$\S g.$ Let the distance (Cp or Ch) of the given angle from the perpendicular be auxiliary a' . Then whether the perpendicular fall within or without the triangle, the *difference* (§ d.) between the side upon which it falls and the auxl. a' is the other segment of that side.

$\S h.$ First, to find the value of B, the arc Cp being auxl. a' ; tang. a' (§ d.) = $\cos C \text{ tang. } b.$

$\S i.$ According to Case II. (§ 198. § r.) $\frac{\text{Rad.}}{\text{tang. } A p} = \frac{\text{Cot. } C}{\text{Sin. } a'}$
 $\frac{\text{Cot. } B}{\text{Sin. } (a \oslash a')}$; and by transposition $\text{Cot. } B = \frac{\text{Cot. } C \text{ Sin. } (a \oslash a')}{\text{Sin. } a'}$
 $= \text{cot. } C \text{ sin. } (a \oslash a') \text{ cosec. } a'.$

$\S j.$ To find the value of A. In the triangle ChB, Ch is auxl. a' ; and tang. $a' = \cos. C \text{ tang. } a.$

$\S k.$ Also, $\frac{\text{Rad.}}{\text{Tang. } B h} = \frac{\text{Cot. } C}{\text{Sin. } a'} = \frac{\text{Cot. } A}{\text{Sin. } (b \oslash a')}$; and by transposition, $\text{Cot. } A = \frac{\text{Cot. } C \text{ Sin. } (b \oslash a')}{\text{Sin. } a'} = \text{cot. } C \text{ sin. } (b \oslash a') \text{ cosec. } a'.$

Whence the general rule for finding either angle.

$\S l.$ The product of $\cos.$ of the given angle (§ h. and § j.) and tang. of the side *opposite* to the required angle, is tang. of auxl. a' . And,

$\S m.$ The *sin.* of the *difference* between auxl. a' and the side *adjacent* to the required angle, multiplied by the *product* of the cosec. of auxl. a' and cotang. of the given angle (§ i. and § h.), is cotang. of the required angle.

$\S n.$ $b=60^{\circ} 0'$ tang. = 0.238561
 $C=27^{\circ} 6'$ cos. = 9.949494 - - cot. = 0.290963

Tang. auxl. a' = 0.188055 = 57^{\circ} 2' 4'' cosec. = 0.076240

$(a' \oslash a) = 52^{\circ} 27' 56''$ sin. = 9.899268

28^{\circ} 25' 54'' Cot. B = 0.266471

§ o. Or, to find the value of A ;
 $a = 109^\circ 30'$ tang. = 0.450851
 $C = 27^\circ 6'$ cos. = 9.949494 - - - cot. = 0.290963

Tang. $a' = 0.400345 = 111^\circ 41' 32''$ cosec. = 0.031898

 $(a \infty b) = 51^\circ 41' 32''$ sin. = 9.894699

 $148^\circ 47' 10''$ Cot. A = 0.217560

§ p. The value of the third side (c) can be found with the help of the same auxiliary a' .

§ q. When the perpendicular falls within the triangle, $\frac{\text{Cos. } A p}{\text{Rad.}}$
 (§ 198. § l.) = $\frac{\text{Cos. } b}{\text{Cos. } a'} = \frac{\text{Cos. } c}{\text{Cos. } (a \infty a')}$; by transposition $\text{Cos. } c =$
 $\frac{\text{Cos. } b \text{ Cos. } (a \infty a')}{\text{Cos. } a'} = \text{cos. } b \text{ cos. } (a \infty a') \text{ sec. } a'$.

§ r. And when the perpendicular (Bh) falls without the triangle,
 $\frac{\text{Cos. } B h \text{ Cos. } a}{\text{Rad.}} = \frac{\text{Cos. } c}{\text{Cos. } (b \infty a')}$; by transposition, $\text{cos. } c =$
 $\frac{\text{Cos. } a \text{ Cos. } (b \infty a')}{\text{Cos. } a'} = \text{cos. } a \text{ cos. } (b \infty a') \text{ sec. } a'$.

N. B. $(a \infty a') = p B$, and $(b \infty a') = A h$.
 Hence the general rule for finding the third side.
 § s. The product of cos. of the given angle, and tangent of either given side, (§ h. & § j.), is tang. of auxl. a' .
 § t. Then (§ q. & § r.) cos. of the same given side, multiplied by the product of sec. of auxl. a' , and cos. of the difference between auxl. a' , and the other given side, is cos. of the required side.

§ u. $C = 27^\circ 6'$ cos. = 9.949494
 $b = 60^\circ 0'$ tang. = 0.238561 - - - cos. = 9.898970

Tang. $a' = 0.188055 = 57^\circ 2' 4''$ sec. = 0.264298

 $(a \infty a') = 52^\circ 27' 56''$ cos. = 9.784786

 $55^\circ 57' 24''$ Cos. c = 9.748049

§ v. Or, taking the tang. and cos. of a ;
 $C = 27^\circ 6'$ cos. = 9.949494
 $a = 102^\circ 30'$ tang. = 0.450851 - - - cos. = 9.523495

Tang. $a' = 0.400345 = 111^\circ 41' 32''$ sec. = 0.432244

 $(b \infty a') = 51^\circ 41' 32''$ cos. = 9.792312

 $55^\circ 57' 24''$ Cos. c = 9.748051

§ w. The difference between the two log. co-sines of c arises from fractions of a second (") , which are in some of the parts operated upon. These fractions may sometimes cause an error of a few seconds (") in the value of the part required.

§ x. There is a method for finding the value of the two angles (A & B) analogous to that under § y. and § z. (§ 199.), for finding two sides. In drawing up formulæ, and selecting methods, for trigonometrical calculations, attention should be paid to what is given, as well as to what is required, in the problem; and that method of solution should be adopted, which equally as correct as others, leads most directly to the result required.

§ y. To find A and B without the help of auxiliaries.

§ z. The cos. of $\frac{1}{2}$ the *sum*, } of the two sides;
Is to cos. of $\frac{1}{2}$ the *difference*, }
As co-tang. of $\frac{1}{2}$ the given angle;
Is to tang. of $\frac{1}{2}$ the *sum* of the required angles.

§ z a. The sine of $\frac{1}{2}$ the *sum*, } of the two sides;
Is to the sine of $\frac{1}{2}$ the *difference*, }
As co-tang. of $\frac{1}{2}$ the given angle;
Is to tang. of $\frac{1}{2}$ the difference of the required angles.

§ z b. $\frac{1}{2}(a+b) = 84^\circ 45' \text{ sec.} = 1.038571$
 $\frac{1}{2}(a-b) = 24^\circ 45' \text{ cos.} = 9.958154$
 $\frac{1}{2} C = 13^\circ 33' \text{ cot.} = 0.617980$

Tang. $\frac{1}{2}$ sum (A & B) = 1.614705 = $88^\circ 36' 32''$

$\frac{1}{2}(a+b)$, co-sec. = 0.001826
 $\frac{1}{2}(a-b)$, sin. = 9.621861
 $\frac{1}{2} C$ cot. = 0.617980

Tang. $\frac{1}{2}$ diff. (A & B) = 0.241667 = $60^\circ 10' 38''$

§ x c. $88^\circ 36' 32'' + 60^\circ 10' 38'' = A = 148^\circ 47' 10''$ } (§ 77. § h.)
And, $88^\circ 36' 32'' - 60^\circ 10' 38'' = B = 28^\circ 25' 54''$ }

§ z d. The following method of finding the value of the third side (c) with the help of an auxl. a' , is useful and of frequent occurrence in nautical calculations.

§ z e. Half the *product* of the sines of the given sides, and *twice* the sine of half the given angle, *multiplied* by the co-sec. of $\frac{1}{2}$ the *difference* between the two sides, is the tang. of auxl. a' .

§ z f. Then the product of co-sec. of a' and said *half product* of the sines of the *three* said quantities, is the sine of *half* the required side.

§ z g.

$$a = 109^\circ 30' \sin. = 9.974347$$

$$b = 60^\circ 00' \sin. = 9.937531$$

$$\frac{1}{2} C = 13^\circ 33' \sin. \times 2 = 18.739522$$

$$2 \cdot 38.651400$$

$$19.325700$$

$$19.325700$$

$$\frac{1}{2} (a \sin b) = 24^\circ 45' \text{ co-sec.} = 0.378139$$

$$\text{Tang. auxl. } a' = 9.703839 = 26^\circ 49' 22'' \text{ cosec.} = 0.345600$$

$$27^\circ 58' 42''$$

$$\text{Sin. } \frac{1}{2} c = 9.671300$$

2

$$c = 55^\circ 57' 24''$$

CASE V.

§ 201. Given the three sides

$$a = 66^\circ$$

$$b = 44^\circ$$

$$c = 30^\circ$$

To find the angles.

§ a. Neither in this, nor in the preceding case, can the value of any one of the unknown

parts be determined by the Catholic Proposition; for the proposed triangle cannot be so divided into two right angled triangles, that two of the given parts shall be contained in either of them.

§ b. This, and the case that immediately precedes it, are particularly useful to the navigator. Some of the most important problems, and those which are of most frequent occurrence in navigation, come under one or both of these cases for solution. The problems, for finding azimuths and the time of day at sea, fall under this case. This and the preceding case are both involved in the calculations for finding the *true*, from the *observed*, lunar distance. Both cases are also involved in finding the latitude by "double altitudes." And by Case IV, the lunar tables in the nautical almanac, are calculated.

§ c. In this, as under the other cases, there are several methods for finding the value of the required part. In all cases the methods, which are the best adapted to practical purposes, are given.

§ d. To find one of the angles (A). The *product* of the co-sec. of the sides that contain the required angle, *multiplied* by the *pro-*

duct of the sine of half the sum of the three sides, and sine of that half sum, less the side opposite the required angle, is double the cos. of $\frac{1}{2}$ the required angle.

§ e. Twice the tang. of $\frac{1}{2}$ the required angle, is the product of co-sec. of $\frac{1}{2}$ the sum of the three sides, and co-sec. of said $\frac{1}{2}$ sum, less the side opposite the required angle, multiplied by the product of the sines of the difference between said half sum and each of the sides that contain the required angle.

$$\begin{aligned} \S f. a &= 66^\circ (\S d.) \\ b &= 44^\circ \text{ co-sec.} = 0.158229 \\ c &= 30^\circ \text{ co-sec.} = 0.301030 \end{aligned}$$

$$\underline{\underline{2)140^\circ}}$$

$$\frac{(a+b+c)}{2} = 70^\circ \text{ sin.} = 9.972986$$

$$\frac{(a+b+c-a)}{2} = 4^\circ \text{ sin.} = 8.843585$$

$$\text{Twice cos. } \frac{1}{2} A = 2)19.275830$$

$$\text{Cos. } \frac{1}{2} A = 9.637915 = 64^\circ 15' 5''$$

2

$$\underline{\underline{A = 128^\circ 30' 10''}}$$

$$\S g. \frac{(a+b+c)}{2} = 70^\circ \text{ co-sec.} = 0.027014 (\S e.)$$

$$\frac{(a+b+c-a)}{2} = 4^\circ \text{ co-sec.} = 1.156415$$

$$\frac{(a+b+c-b)}{2} = 26^\circ \text{ sin.} = 9.641842$$

$$\frac{(a+b+c-c)}{2} = 40^\circ \text{ sin.} = 9.808068$$

$$\text{Twice tang. } \frac{1}{2} A = 2)20.633339$$

$$\text{Tang. } \frac{1}{2} A = 10.316669 = 64^\circ 15' 5''$$

2

$$\underline{\underline{A = 128^\circ 30' 10''}}$$

§ h. In all cases § g. is a good solution. But when the required angle (A) is near 180° , (§ 176. § c.) solution § f. will not carry great accuracy into the result. But this seldom occurs in practice, and in most cases either solution may be adopted with success.

§ i. One of the angles being found, the two others (§ 144.) are determinable.

CASE VI.

§ 202. Given the three angles,

$$A = 114^\circ$$

$$B = 39^\circ$$

$$C = 49^\circ$$

To find the value of the sides.

§ a. This problem is but of little practical utility to the navigator, for problems in

which the three angles of a triangle are the data, seldom occur. But there are several methods by which the side required may be found; one of which, being general in its application, is thought sufficient.

§ b. The *product* of *cos.* of the difference between half the sum of the three angles, and each angle adjacent to the required side, multiplied by the *product* of *co-sec.* of each of said angles, is twice the *cos* of $\frac{1}{2}$ the required side.

§ c. To find the value of a .

$$\frac{(A+B+C)}{2} - B = 62^\circ \text{ co-sine} = 9.671609$$

$$\frac{(A+B+C)}{2} - C = 52^\circ \text{ co-sine} = 9.789342$$

$$B = 39^\circ \text{ co-sec.} = 0.201128$$

$$C = 49^\circ \text{ co-sec.} = 0.122220$$

$$\text{Twice cos. of } \frac{1}{2} a = 2) 19.784299$$

$$\text{Cos. } \frac{1}{2} a = 9.892149 = 38^\circ 43' 50''$$

$$a = 77^\circ 27' 40''$$

§ d. The value of one side being known, that of the others is determinable.

NAUTICAL ASTRONOMY.

NAUTICAL ASTRONOMY.

§ 203. That part of astronomy which treats of the motions and of the positions of the heavenly bodies, is an important branch of navigation. A knowledge of these motions and positions is highly essential to the navigator; for it is by understanding them, that methods have been devised for determining latitude and longitude at sea, by means of observations made upon the heavenly bodies.

§ 204. The figure of the earth is that of an oblate spheroid. It resembles that which would be described by the revolution of a semi-ellipse about its minor axis. It is flattened in at the poles, and elevated towards the equator.

§ 205. To suit the common purposes of navigation, the earth may be considered as a perfect sphere; the sun as the centre of the universe, and the centre of motion in the planetary system; the fixed stars may be considered to be almost stationary, and immeasurably distant from the earth and from each other; from every part of the earth's orbit, they are seen in the same relative positions, with regard to each other.

§ 206. The earth has two rotary motions; one about its axis, which produces day and night; the other in its orbit, and around the sun, which causes the seasons.

§ a. The latter is called the earth's annual, and the former its diurnal, motion.

§ 207. In its annual revolution around the sun, the earth describes the periphery of an ellipse.

§ a. The centre of the sun is in the plane, and at one of the foci of this ellipse, and the centre of the earth moves on its circumference.

§ 208. The axis of the earth is inclined, from a perpendicular to the plane of its orbit, nearly at an angle of $23^{\circ} 28'$.

§ a. If the earth's axis were perpendicular to this plane, there would be no change of seasons, or variation in the length of day and night; and at either pole there would be continual day.

§ b. It is this angle of inclination which causes the *declination* of the sun.

§ c. In a northern winter, the earth is nearer to the sun than it is in summer; but owing to the sun's declination, or the inclination of the earth's axis to the plane of the earth's orbit, the south pole is turned towards the sun during the former season, and the sun's rays striking the northern hemisphere more obliquely than they do in

summer, are in consequence, spread over a greater surface, and are therefore less effective in producing heat.

§ 209. The earth revolves from west to east. It completes one revolution on its axis in a day, and one around the sun in a year.

§ 210. The periphery of the earth's orbit, like the circumference of every re-entering curve, contains 360° .

§ a. The earth completes one revolution in its orbit, in *365d, 5h, 48m, and 48s*.

§ b. Therefore, the motion of the earth in its orbit, in one day, is, as *365d, 5h, 48m, 48s* is to 360° ; the ratio of which is $59' 8''$.

§ 211. An *astronomical, sea or civil, day*, is the time between two consecutive noons, or midnights.

§ 212. A *sidereal day* is the time between two consecutive transits of a star across the same meridian.

§ 213. The intervals of time from the passage of the sun and a star across, until their return to, the same meridian, are unequal. The difference between these intervals, results from the combined effect of the earth's motion about her axis, and in her orbit; for, during the interval between two consecutive transits of a star across the same meridian, the earth advances in its orbit (§ 210. § b.) nearly $59' 8''$; so that the transit meridian has to go $59' 8''$ more than one complete revolution around the axis of the earth, before it returns to the sun.

§ a. Thus, during the time in which the earth is making one complete revolution in its orbit, a star has one transit more than the sun has, across any proposed meridian.

§ b. Sidereal accelerates upon *mean solar time*, *3m, 56s.55* in *24h*, or about $9\frac{1}{2}s$ in an hour.

§ 214. The motion of the earth about its axis, is uniform; but the velocity of the earth in its orbit, is irregular. This irregularity is caused by the variation in the mutual action of the centrifugal and centripetal forces upon the earth.

§ a. The sidereal day is consequently of a uniform length; and the solar day varies with the velocity of the earth in its orbit.

§ b. This variation produces *equation of time*.

§ 215. *Apparent time* is the time which is deduced by calculation, from the bearing, or the altitude of the sun.

§ a. The time shown by a dial, is apparent time.

§ 216. *Mean time* is the average of apparent time.

§ a. Watches, etc., are designed to keep mean time.

§ 217. *Equation of time* is the difference between mean and apparent time.

§ 218. If the motion of the earth in its orbit, were uniform, describing equal arcs in equal times, there would always be the same length of time from one transit of the sun to another, across the same meridian; and apparent and mean time would always agree. But from noon to the succeeding noon, there is sometimes more, and sometimes less, than 24 hours.

§ a. Twenty-four hours is the average, or mean of the time, in

which, during one complete revolution of the earth in its orbit, the sun performs every one of its 365 transits across the same meridian.

§ *b*. This is the time which all good time pieces show. The time shown by them and the sun agrees only four times during a year; when this agreement takes place, then there is no equation of time.

§ 219. All astronomical calculations, such as those in the nautical almanacs, etc., are computed for astronomical time.

§ *a*. Of those in the ephemeris, some are for *mean*, and some for *apparent* astronomical time.

§ 220. An astronomical day commences when the centre of the sun is on the meridian (say of Greenwich), and ends, when it returns to the same meridian.

§ *a*. An astronomical day is divided into 24 hours, which are reckoned in succession, from 1 up to 24.

§ 221. A civil day commences at the midnight, that *precedes* the beginning of the astronomical day.

§ *a*. A civil day is divided into two equal portions; the first is A.M.; it ends at noon, when the astronomical day begins: the latter is P.M.; it ends at midnight, when the succeeding day begins. Each division consists of 12 hours.

§ *b*. Consequently, the day civil, is always 12 hours in advance of the day astronomical. Thus, Dec. 11th, 9h 34m 44s A.M. is, according to astronomical time, Dec. 10th, 21h 34m 44s; and 16 hours of civil time, or Dec. 11th, 4h P.M., is Dec. 11th, 4h, according to the astronomical time. Therefore, when the civil time is A.M. 12 hours added to it makes it astronomical time.

§ 222. The *ecliptic* is a great circle, the centre of which is that of the earth, and the plane of which coincides with the plane of the earth's orbit. Therefore these planes cut the axis of the earth at the same angle.

§ 223. The sun is always in the ecliptic.

§ *a*. Considering the earth to be stationary in its orbit, the sun appears to perform an annual revolution, moving around the earth, on the periphery of the ecliptic, and crossing the equator twice during the year.

§ 224. The ecliptic is divided into 12 arcs, of 30° each. These divisions, named and marked, are called the Signs of the Zodiac. They are—

§ *a*. Aries (♈), Taurus (♉), Gemini (♊), Cancer (♋), Leo (♌), Virgo (♍), Libra (♎), Scorpio (♏), Sagittarius (♐), Capricornus (♑), Aquarius (♒), and Pisces (♓).

§ *b*. The first six being north of the equator, are called *northern signs*.

§ *c*. The other six are south of the equator, and are called *southern signs*.

§ 225. The points in which the ecliptic (§ 223. § *a*.) crosses the equator, are called the *equinoctial points*; because, when the sun passes through these points, the days and nights are equal.

§ 226. The sun crosses the equator, and enters the first point of

Aries, about the 21st of March. The sun then passes through **Aries**, **Taurus**, and **Gemini**, towards the north; and about the 21st of June, it reaches its greatest northern declination at the first point of **Cancer**, where it appears to be stationary for a while; it is then said to be in the *summer solstice*.

§ a. The first point of **Cancer**, is a *solstitial point*.

§ b. Returning thence, towards the south, the sun passes through **Cancer**, **Leo**, and **Virgo**, and completing its tour, or the north side of the equator, it arrives, about the 23d of September, at the intersection of the ecliptic with the equator, when the day and night are again equal, and the sun is in the *autumnal equinox*.

§ c. Recrossing the equator then, the sun enters the first point of **Libra**, and continuing on towards the south, it *descends* through **Libra**, and the succeeding signs, and reaches its greatest southern declination, about the 22d of December; then it is at the first point of **Capricorn**, and again appears to stand still.

§ d. The sun is now in its winter solstice; and returning towards the north, it *ascends* through **Capricorn**, **Aquarius**, and **Pisces**, and entering the first point of **Aries**, completes one annual revolution, and goes on to renew the seasons.

§ 227. The time from the sun's passing the first point of **Aries**, until its return to that point again, is about (§ 210. § a.) 365d 5h 48m 48s.

§ a. This is called a *solar*, or a *tropical year*, and it is the year by which the seasons are regulated.

§ b. A solar, differs from a sidereal, year, about 20m 23s.

§ 228. A *sidereal year* is the time from the sun's leaving, until its return to, the same part of the heavens, or to the same fixed star.

§ a. A sidereal, is longer (§ 227. § b.) than a solar, year, on account of the *precession* of the *equinoxes*, which is a motion contrary to that of the sun through the signs.

§ b. While the sun is completing a revolution from left to right through the signs in successive order, they are moving in the contrary direction, or from right to left, and by the time the sun has returned to the first point of **Aries**, for instance, this point will have retrograded a little more than 51"; and, on account of this motion, the sun comes to this point sooner than it would have done, had the first point of **Aries** remained stationary.

§ 229. The *zodiac* is a belt in the heavens that extends 8° on each side of the ecliptic.

§ a. The orbits of all the primary planets are within the zodiac.

§ 230. The *primary planets* are **Mercury**, **Venus**, the **Earth**, **Mars**, **Jupiter**, and **Saturn**.

§ a. There are five other planets, but they cannot be seen with the naked eye. They are called *telescopic planets*.

§ 231. The points in which the orbit of a planet cuts the ecliptic, are called *nodes*.

§ a. That node is called the *ascending node* (Ω), through which

the planet passes, as it crosses the ecliptic, going from the south to the north side of it.

§ *b.* The other point of intersection is called the *descending node* (Ω).

§ 232. The *equator*, or *equinoctial line*, is a great circle, whose plane divides the earth into two equal parts.

§ *a.* These parts are called the northern and southern hemispheres.

§ *b.* The centre of the earth is the centre of the equator, and of all the *great circles used in nautical astronomy*.

§ 233. The *poles* (§ 123.) of the equator, also called the *Poles*, are two points on the earth, that are diametrically opposite to each other; each is 90° from the equator.

§ *a.* The one on the north side of the equator, is the *north pole*; and that on the south side, is the *south pole*.

§ 234. A straight line from one pole to the other, passes through the centre of the earth, and (§ 124.) is called the *axis* of the earth.

§ *a.* Around this axis, the earth performs its diurnal revolutions.

§ 235. From the best measurements, the equatorial appears to be about 26 miles greater than the polar diameter of the earth. And the degrees of latitude increase in length from the equator towards the poles.

§ *a.* The surface of the earth (§ 204.) being flattened in at the poles, and elevated at the equator, its meridional curvature is less near the former than it is near the latter; consequently a degree of latitude near the poles contains more fathoms, feet, etc., than one at or near the equator.

§ 236. Suppose the plane of the equator to be extended to the heavens; it there forms the *celestial equator*, and its poles, are the *poles* of the world.

§ 237. The latitude of places on the earth, is measured from the terrestrial equator; and their longitude is measured on it.

§ *a.* In the heavens, the declination of the bodies are measured from the celestial equator, and their ascension on it.

§ *b.* Declination and ascension are, in the heavens, what latitude and longitude are on the earth.

§ 238. The sun crosses the equator twice in a year.

§ *a.* While the sun is on the north side of the equator, the sun is constantly visible from the north pole, and daylight continues there until after the sun recrosses the equator, when the sun goes below the horizon, and does not rise again, until (§ 226. § *d.*) completing its southern tour, it is approaching the vernal equinox.

§ 239. The year, instead of being divided into seasons at the poles, may, more properly, be divided into day and night; for there is but one day and one night at each pole during the year.

§ *a.* At the north pole, the day commences about the 21st of March, when the sun crosses the equator, and continues until the sun recrosses the equator, which happens about the 23d of September, when night succeeds the day, and day begins at the south pole, and lasts until the sun again returns to the first point of Aries.

§ *b*. Owing to atmospheric refraction, the sun may be seen at either pole for several days previously to its rising above, and after it has gone below, the natural horizon.

§ 240. The morning and evening twilights at either pole, are together about two months and a half long.

§ *a*. When the sun crosses the *crepusculum*, the twilight begins and ends.

§ 241. *Crepusculum* is a small circle parallel to the horizon, and 18° below it.

§ 242. All small circles that are parallel to the horizon, are *almacanters*.

§ *a*. To an observer at the north, or south pole, the horizon and the equator coincide, and the parallels of declination are *almacanters*.

§ *b*. At the north pole, the *crepusculum* coincides with the parallel of the 18th degree of southern declination, which the sun crosses about the 29th of January, (near 51 days before it rises;) and on the 13th of November, (near 50 days after it has gone down).

§ *c*. On account of such long twilights, the winter nights, in high southern or northern latitudes, are rendered less gloomy than they otherwise would be.

§ 243. The earth is divided into five *zones*; two frigid, two temperate, and one torrid.

§ *a*. The torrid zone is the largest; it extends to the parallels of $23^\circ 28'$ north and south latitude; consequently it is $46^\circ 56'$ broad.

§ *b*. The small circles which limit it, pass through the solstitial points, and are called *tropics*, from *trepho*, (Gr.); because, when the sun reaches the parallel of declination for $23^\circ 28'$ (§ 226. § *b*. & § *d*.) it appears to turn its course, and to recede from the pole which it was approaching, and to retrograde towards the direction whence it came.

§ *c*. That parallel which is north of the equator, (§ 226.) is the *tropic* of Cancer.

§ *d*. And that on the south side of the equator, (§ 226. § *c*.), is the *tropic* of Capricorn.

§ *e*. The sun is vertical twice a year, at every place within the tropics.

§ 244. Each of the temperate zones extends over $43^\circ 4'$ of latitude.

§ *a*. That on the north side of the equator, called the north temperate zone, extends from the *tropic* of Cancer to the arctic circle.

§ *b*. And the south temperate zone extends from the *tropic* of Capricorn to the antarctic circle.

§ 245. The *arctic* and *antarctic* are small circles, parallel to the equator, and $23^\circ 28'$ from the poles.

§ *a*. The arctic is about the north, and the antarctic about the south pole.

§ *b*. They are sometimes called the *polar circles*.

§ 246. The *frigid* zones are between the polar circles and the poles.

§ 247. *Latitude* is distance on the earth, measured north or south, from the equator.

§ 248. *Meridians* are great circles, that are secondaries to the equator.

§ a. Therefore (§ 126. § a. & § 127.) they cut it perpendicularly, and intersect each other at the poles.

§ b. The arc of a meridian that is contained between a place and the equator, measures the latitude of that place.

§ c. The meridian of an observer passes through his zenith.

§ 249. *Parallels of latitude* are small circles, parallel to the equator.

§ a. All places upon the same parallel have the same latitude.

§ b. And all places that are on the same meridian, are in the same longitude.

§ 250. *Circles of longitude* are meridians.

§ 251. *Elevation of the pole* is the distance of either pole above the horizon of any observer.

§ a. This distance is measured on the meridian of the observer; it is equal to his latitude.

§ 252. *Longitude* is the distance, expressed in degrees, etc., between two meridians. It is measured on the equator, and east or west from a meridian.

§ a. A meridian from which longitude is measured, is called the *prime meridian*.

§ b. The location of this meridian is optional with topographers. The French reckon the longitude of all other places from the meridian of Paris; the Spaniards from Cadiz. The English use the meridian of the Royal Observatory at Greenwich for their prime meridian: and the Americans generally construct their charts from the meridian of Washington City.

§ c. But as long as most of the charts and the tables of the Nautical Almanac which we use, shall be constructed and calculated to the meridian of the Greenwich observatory, it will be found more expedient to reckon longitude from this, as the prime meridian.

§ 253. It is to be wished that all nations would fix upon one common prime meridian. One might be established from celestial phenomena, by which all that is arbitrary in its locality, might be made to disappear. La Place recommends the adoption of a universal first meridian, and suggests the propriety of selecting for this purpose, that meridian, upon which it was 12 o'clock when the sun entered the point of the vernal equinox in the year (1250), in which the apogee of the earth's orbit coincided with the solstitial point in Cancer. Such a universal meridian would pass about 8 miles west of Cape Mesurada on the Coast of Africa.

§ 254. The longitude of a place is measured on the arc of the equator, which is contained between the meridian of that place, and the prime meridian.

§ a. The angle at either pole, which these two meridians make with each other, is equal to the longitude.

§ b. Consequently the arc of a parallel of latitude (§ 249.), which

Not at the time of its first

1845. 11. 12.

is intercepted between that place and the meridian of any other place, contains, in degrees, the difference of longitude between these two places.

§ c. The difference of latitude between two places, is the arc which is contained on the meridian of either place, between the parallels of latitude of these two places.

§ 255. *Declination* is the distance of a heavenly body from the equatorial plane.

§ a. Declination is north or south, according as the body is north or south of the equator. It is measured in the heavens, as latitude (§ 248. § b.) is on the earth.

§ b. The arc of the circle of declination or of right ascension, that is contained between the equator and the centre of the body, measures its declination.

§ 256. *Circles of right ascension* or of *declination* in the heavens, correspond with meridians of terrestrial longitude.

§ a. They cut the equator at right angles, and intersect each other in the poles of the world.

§ 257. *Parallels of declination* are small circles in the heavens, that are parallel to the equator.

§ a. They correspond with parallels of latitude on the earth.

§ b. The tropics (§ 243. § c. & § d.) are the parallels of the sun's greatest declination.

§ 258. *Polar distance* is the distance of any celestial body from either pole.

§ a. It is the arc of the circle of declination that is contained between the body and either pole.

§ b. The complement of the declination of a heavenly body, expresses its polar distance.

§ 259. The *right ascension* of a body is the arc of the equator, which is between the first point of Aries and the circle of the declination of that body.

§ a. This arc is always counted in the order (§ 224. § a.) of the signs, and its dimensions are expressed in hours, minutes, and seconds.

§ 260. Right ascension in the heavens, is what longitude is on the earth. But the manner of reckoning them is different.

§ a. Longitude is reckoned from the prime meridian as far as 180° both east and west.

§ 261. Right ascension commences to be reckoned from the first point of Aries, and goes entirely around, in the direction in which the sun passes through the signs.

§ 262. The ascensional difference of the sun, is the difference between its right and oblique ascension, or between sunrise and 6 o'clock.

§ 263. *Horary angles* are those which meridians, or circles of declination, make with each other at the poles.

§ a. The *6 o'clock hour circle*, is that circle of declination (§ 256. § a.) which cuts the equator and the horizon in the east and west points.

§ *b*. It is secondary to the equator and to the meridian of the observer.

§ *c*. Any circle of declination is an *hour circle*.

§ 264. *Celestial latitude* is distance between the ecliptic and any body in the heavens; it is measured from the ecliptic, and upon a secondary to it.

§ 265. The secondaries of the ecliptic, are circles of celestial longitude.

§ *a*. The arc of the circle of celestial longitude, that lies between the ecliptic, and a body in the heavens, measures in degrees, etc., the latitude of that body.

§ 267. The longitude of heavenly bodies is reckoned on the ecliptic, as right ascension is on the equator (§ 259.).

§ *a*. It commences at the first point of Aries, and is reckoned around in the direction in which the sun passes through the signs.

§ 268. The right ascension and longitude of an object are never the same, except when the body is on the solstitial colure, which cuts both the ecliptic and the equator at right angles, and passes through their poles.

§ 269. The *solstitial colure* is that circle of declination which passes through the solstitial points (§ 228. § *a*. & *c*.).

§ 270. The *equinoctial colure* is the circle of declination, which passes through the equinoctial points (§ 228. § *b*.).

271. The equinoctial and the solstitial points are the four *cardinal* points of the heavens.

§ 272. The four *cardinal* points of the horizon are the east and west, and the north and south points.

§ *a*. The *east* and *west* are the points in which the equator and the horizon intersect each other.

§ *b*. The *north* and *south* are the points in which the meridian of the place cuts the horizon.

§ 273. Every observer has two horizons, one *rational*, the other *sensible*.

§ *a*. The eye is the centre of the latter, and is on the axis of the former.

§ 274. The *sensible horizon* is that circle which terminates the view upon an uninterrupted plane.

§ *a*. It is formed by the apparent meeting of the plane upon which we stand, with the concave expanse above.

§ *b*. It is a small circle, and is parallel to the rational horizon.

§ *c*. The circle which terminates our view at sea, is the *sensible horizon*.

§ 275. The *rational horizon* is a great circle; its plane passes through the centre of the earth, and its axis through the eye of the observer. Suppose $H a F$ to be half of the earth, $D Z C$ the concave blue which bounds the vision, and $D H C$ the plane of the rational horizon. If an observer were placed at the centre (G) of the earth, the angle $D G Z$ would show the altitude of an object in the zenith, at Z , from the rational horizon. If the observer were placed at the circumference (at a) of the earth, $p a p$ would be the plane

S

of his visible horizon, and the angle $p a Z$ ($= D G Z \text{ } \S 30.$) would show the altitude of a body at Z , from the sensible horizon. But if the observer were placed at A above the surface of the earth, the angle $B A Z$ ($> D G Z$) would show the altitude of Z from his sensible horizon.

§ a. When the eye is elevated above the level of the sea, (as at A ,) the line of vision AB to a point B in the sensible horizon, cuts the plane CD of the rational horizon at an angle, DEB , which angle is called the *dip*. Consequently, when the eye is above the surface of the plane on which we stand, the sensible horizon is *below* the rational horizon.

§ b. The poles of the rational horizon are the zenith and nadir.

§ 276. The *zenith* is the point in the heavens which is directly over head.

§ a. Being a pole of the horizon, the zenith is 90° from the horizon.

§ 277. The *nadir* is the other pole of the horizon; it is in the lower part of the heavens, directly under our feet, and diametrically opposite to the zenith.

§ 278. *Azimuth* circles are secondaries ($\S 127.$) to the horizon; cutting it perpendicularly, they intersect each other in the zenith and nadir.

§ a. They are also called *vertical* circles.

§ 279. The azimuth circle which cuts the horizon in the east and west points, is called the *prime vertical*.

§ a. The prime vertical of every observer, is secondary to his meridian.

§ 280. The altitude, and zenith distance of a heavenly body, are measured on its azimuth circle.

§ 281. The *zenith distance* of a heavenly body is its distance from the zenith of the observer; thus, Zs (§ 275.) is the zenith distance of the star at s .

§ *a*. It is measured on the arc of the azimuth circle, which lies between the centre of that body and the zenith.

§ *b*. The *zenith distance* is *north* when the body is south of the observer.

§ *c*. And south, when the body is north of the observer.

§ 282. The *altitude* of a heavenly body, is its distance above the horizon.

§ *a*. The arc of the azimuth circle which is contained between the centre of a body and the horizon, measures the altitude of that body; thus, Ds (§ 275.) is the altitude of the star at s .

§ *b*. The complement of the altitude of a body, gives its zenith distance.

§ 283. The altitude which is taken of the sun or moon, with a quadrant or sextant, is the observed *altitude* of one of the edges, called a *limb*.

§ *a*. The apparent altitude of the *centre* is found by applying the corrections, (which are laid down in the Nautical Almanac,) for the semidiameter of the body, to the apparent altitude of its limb.

§ *b*. And the *true*, is obtained from the *apparent* altitude of the centre, by applying to the latter, corrections for the parallax and refraction, which are also known by previous calculations.

§ *c*. The apparent and the true altitude of a body, are always measured on the same azimuth circle.

§ 284. The rays of light coming from the heavenly bodies strike the atmosphere obliquely, and entering from a rarer into a denser medium, are refracted, or *bent downwards*; this causes the body whence they emanate to appear higher up in its azimuth circle than it really is. Suppose $*e$ (§ 275.) be a ray of light from $*$, and Ao to represent the atmosphere; when this ray strikes the atmosphere, it will be refracted so as to reach the eye of the observer at a , in the direction ae , which makes $*$ appear at s , above its true place.

§ *a*. Hence the apparent altitude of the sun or a star is always greater than the true altitude, unless the body be in the zenith.

§ 285. Parallax has a contrary effect; it acts in a direction opposite to that of refraction, and causes a body to appear *lower* down in its azimuth circle than it really is.

§ *a*. But the effects of parallax and refraction, though acting in contrary and opposite directions, seldom counterbalance each other, so as to make an object appear in its true place.

§ 286. The parallax of the moon is always greater than the refraction; and the moon always appears below its true place.

§ *a*. Hence the apparent, is always *less* than the true altitude of the moon.

§ 287. The *horizontal parallax* of a body, is the difference between the *true* and *apparent* place of that body, (supposing there be no refraction), when it is in the horizon.

§ *a*. The horizontal parallax is equal to the angle at the body,

which is subtended by the distance of the observer, from the centre of the earth.

§ *b*. The angle which this distance, or semidiameter, subtends, is greatest when the body is in the plane of the rational horizon; thus, the parallax of a body at *D*, (§ 275.) is the angle $G D a$; and the parallax of the same body, when at *s*, is $G s a$.

§ *c*. As the object rises above the horizon, the angle which this semidiameter subtends, is called *parallax in altitude*; it gradually decreases until the object reaches the zenith, when it vanishes.

§ *d*. The nearer the object is to the earth, the greater will this angle be at the centre. Hence the moon's parallax is greater than the sun's, and this greater than that of the fixed stars.

§ 288. The parallax of a body decreases from the horizon to the zenith, in the proportion of sine of the zenith distance (§ 281.) to radius.

§ 289. Owing to the effects of parallax and refraction upon the heavenly bodies (§ 285. § *a*.), they are never seen in their *true* places, except when in the zenith.

§ *a*. The places in which the heavenly bodies are seen, are called their *apparent places*.

§ 290. The *true place* of a heavenly body, is that place in which it would appear, if seen from the centre of the earth.

§ 291. The *azimuth* of a celestial body is the angle which is contained at the zenith, between the meridian of the place, and an arc of the azimuth circle, which passes through the centre of that body.

§ *a*. In north latitudes, the angle on the *north* side, and in south latitudes, the angle on the *south* side, of the arc of this azimuth circle, is called the azimuth.

§ *b*. Before a body crosses the meridian of the observer, its azimuth is east, and west afterwards.

§ *c*. Thus, in north latitude, an azimuth is said to be *north*, so many degrees east, if the body be east of the meridian; or *N*, so many degrees west, if it have passed the meridian.

§ *d*. And in south latitude, the azimuth is reckoned in the same manner from the south point, to the east or west.

§ 292. The *amplitude* of a celestial object, is the arc of the horizon that lies between the east or west point, and the centre of that object when it is rising or setting.

VARIATION OF THE COMPASS.

§ 293. The variation of the needle, is determined by means of azimuths, or amplitudes.

§ 294. The needle does not always point to the north and south poles. At some places it points to the east, and at others to the west, of the true north and south points.

§ *a*. Even at the same place, the polarity of the needle does not remain constant.

§ *b*. As to the direction in which the needle points, it is subject to certain periodical changes, which do not follow any known laws.

At some places, after having pointed, for several years, to the eastward of the true north, it has gradually pointed nearer to the north point, until its position lay due north and south; then crossing the direction of the meridian, the needle has continued to turn more and more to the westward of the true north, until it has attained the maximum of its deviation for that place, when, after having remained stationary for a time, it commenced its return towards its former position.

§ 295. *Variation* of the compass is the deviation of the needle, from pointing to the north and south poles.

§ 296. The points to which the needle tends, are called the *magnetic* north and south points.

§ 297. When the northern point of the needle, or the N point on the compass card, points to the eastward, or to the *right*, of the true north, the variation is *easterly*.

§ *a.* And *westerly* when the same point points to the *left*, or to the westward of the true north.

§ 298. The true direction of the magnetic north point, is found by applying the variation, when it is easterly, to the *right* of the true north; and to the *left* of the *true* north, when the variation is westerly.

§ *a.* Thus, when the variation is one point easterly, the north point of the needle, or the N point on the compass card, points N. by E. And it points N.N.W. when the variation is two points westerly.

§ *b.* Wherefore, knowing the magnetic bearing of any object, its true bearing may be determined, by applying the variation, when easterly, to the *right* of its compass bearing; and to the *left*, when the variation is westerly.

§ *c.* The true bearing of an object, that bears east per compass, is E. by S. if the variation be one point easterly; but E. by N. if the variation be one point westerly.

§ 299. The cause of variation, as well as of the attraction of the needle, towards the poles, is unknown.

§ 300. The needle is subject to the influence of another power equally mysterious in its nature; it is called *local attraction*.

§ *a.* This attraction operates on ship-board, and with different effects in different latitudes, as well as in the different directions in which the vessel may be heading,

§ *b.* Its effects upon the needle become obvious by taking the bearing of a fixed point on shore, then swinging the ship entirely around, and observing at several different points of her heading, the bearing of said fixed point.

§ *c.* The effect of local attraction upon the compass, is not often taken into consideration by navigators, although on board of vessels in some latitudes, (as in the English channel), it is said to cause the needle to deviate several degrees. The loss of fleets has been ascribed to the neglect of this attraction, on the part of navigators. A. B.

§ *d.* In conducting surveys particular attention should be paid to the effect of local attraction upon the needle.

§ 301. A *magnetic* meridian is a great circle that passes through the magnetic north and south points, and through the zenith of the observer.

§ *a*. The needle always lies in the direction of this meridian.

§ *b*. Magnetic meridians cross each other in the magnetic poles.

§ 302. The *magnetic* equator is a secondary to all magnetic meridians.

§ 303. The *magnetic* prime vertical is a secondary to the magnetic meridian of the observer.

§ *a*. It passes through the zenith and the magnetic east and west points of the horizon.

§ 304. The *magnetic* azimuth of a celestial body, is an angle at the zenith, that is contained between the magnetic meridian of the observer and the zenith distance of the object, when its bearing is taken.

§ *a*. The magnetic azimuth should always be reckoned from the nearest pole, around towards the east, when the object is on the east side of the meridian of the observer; and to the west, after the object has crossed the meridian.

§ *b*. The advantage of reckoning the magnetic azimuth in this way, consists in having the true and magnetic azimuth always of the same name; i. e. either both east, or both west.

§ 305. The *magnetic* amplitude of a celestial body, is that arc of the horizon, which lies between the centre of the body, when the body is in the horizon, and the magnetic east or west point, according as the body is rising or setting.

§ 306. Upon the magnetic equator, the needle assumes a horizontal position.

§ *a*. To the north or south of this equator, it points *downwards*, inclining towards the nearest magnetic pole.

§ 307. The angle of this inclination of the needle, below the plane of the horizon, is called the *dip* of the needle.

§ *a*. The maximum of the dip is at the magnetic poles, and the minimum at the equator.

§ *b*. The ratio of the increment in dip, from the equator, towards the poles, has never been satisfactorily established.

§ 308. The variation of the compass is found by ascertaining the true and magnetic azimuths, or amplitudes, of any celestial object at the same moment.

§ *a*. The difference between them is the variation.

§ 309. The magnetic azimuth, or amplitude of a celestial object, is found by taking its bearing with an azimuth compass.

§ 310. The true azimuth or amplitude of a celestial object is determined by trigonometrical calculations.

§ *a*. The usual data for this operation, are the co-latitude of the observer, and the zenith, and polar, distances of the object.

§ 311. In North Latitude; the variation is easterly, if the magnetic, be less than the true, azimuth, when the object is on the east side of the meridian; or the variation is easterly, if the magnetic be the greater azimuth, when the object is west of the meridian.

§ *a*. And in South Latitude; the variation is easterly, when the magnetic is the greater azimuth in the former, and the less in the latter case.

§ 312. In each case, *mutatis mutandis*, the variation is westerly.

§ 313. *Stereographic projection* is the most useful, and being the most natural, is the most simple mode of representing a sphere, or circles of a sphere, upon a plane.

§ 314. In stereographic projection the eye is supposed to be at some point on the surface of the sphere, and to see one half of the sphere.

§ a. The circle which terminates the vision is called, in projection, the *primitive circle*.

§ b. The eye is the centre of this circle, and is the *projecting point*.

§ 315. The diagrams for the purposes of nautical astronomy, in this treatise, are projected upon the plane of the horizon.

§ 317. This Fig. is a stereographic projection upon the } Plate 2.
plane of the horizon, in lat. 40° north.

§ a. A, the projecting point, represents the centre of the horizon W N E S, as well as the zenith and the eye of the observer; P, the pole of the observer; P N (§ 251.) the elevation of the pole; W Q E (§ 232.) the equator; A Q (§ 248. § b.) the latitude of the observer; and A P the complement of his latitude; W A E (§ 279.) his prime vertical; N P S (§ 248. § c.) his meridian; A B I (§ 278.) the azimuth circle of the body whose altitude is taken; B I and A B (§ 280.) its altitude and zenith distance; *d e c* (§ 257.) the parallel of its declination; P B (§ 258. § a.) its polar distance, and P B H (§ 256. § a.) is an arc of its circle of declination; A P B (§ 263.) is the horary angle at which the body is; B A P (§ 291.) is its azimuth; N, E, S, and W, (§ 272.) are the cardinal points of the horizon; and W P E (§ 263. § a.) is the six o'clock hour circle.

§ b. It is easily conceived how it is, that, of all circles which cut the primitive circle of a projection, only that part of their circumference which is above the primitive, can be seen from the projecting point; and that 180° of every arc of these circles, that are great circles, is above (§ 125. § a.) the horizon or plane of projection.

§ c. And consequently that all of these arcs will appear in the projection to be more straightened out, or of less curvature than the primitive circle; and this curvature will be in proportion inverse to the obliquity with which their planes cut the plane of the primitive.

§ d. The less obliquely these planes cut the plane of the horizon, the more obliquely the observer at A looks upon them, and consequently the less their arcs appear to be curved, until, looking upon the edge of the planes of those which pass through his zenith, they appear as straight lines.

§ 318. In these projections, every great circle (N P S, W A E,) which passes through the zenith, is represented as a straight line.

§ a. And the length of every line (A N, A I, etc.) included between the projecting point (A) and the circumference of the primitive, measures 90° , and is considered as the quadrant of a circle.

§ 319. All of those circles which cut the plane of the primitive obliquely, and whose arcs (W Q E, P B, etc.) appear in the pro-

jection, to be of less curvature than the primitive, are called *oblique circles*.

Plate 2. { § 320. And those circles, whose arcs (N P S, W A E,) pass through the zenith (§ 318.) are called *right circles*.

§ a. With the horizon as the primitive circle; the meridian, (§ 248. § c.), prime vertical, (§ 279. § a.), and azimuth circles (§ 278.), pass through the zenith, and appear upon the plane of projection (§ 318.) as right circles.

§ 321. In lat. 40 N., the sun's declination being 20° S.; its magnetic azimuth was N. 119° 25' E. in the morning, when its true altitude was 16° 48' 25''; required the sun's true azimuth, and the variation of the compass.

§ 322. W N E S, (§ 316. § a.) represents the horizon of the observer; A, the centre of it, his zenith, and the place at which he stood to take the observation; *n A s*, the magnetic (§ 301.) meridian; and (§ 308. § a.) N A *n* is the variation.

§ a. The co-lat. (A P), the zenith, and the polar distance, (A B, P B) (§ 317. § a.), are the sides of the triangle A P B, and (§ 321.) are the given parts; and the azimuth P A B, is the required part; the value of it is determined according to Case V, (§ 201. § d.)

§ b. In the formulæ for calculation,

P D, stands for polar distance.

Z D, " zenith distance.

Co-lat. " complement of the latitude of the place of observation.

§ c. The complements of what is given (§ 321.) constitute the data of the proposed triangle.

§ d. $b = 50^\circ$ - = Co-lat.

$p = 73^\circ 11' 35'' = Z D$

$a = 110^\circ$ - = P D

To find the azimuth P A B, (§ 201. § f.)

§ e. a , or P D = 110°

p , or Z D = $73^\circ 11' 35''$ co-sec. = 0.018959

b , or Co-lat. = 50° - co-sec. = 0.115746

Sum 2) $233^\circ 11' 35''$

$\frac{1}{2}$ Sum = $116^\circ 35' 47''$ sin. = 9.951426

$\frac{1}{2}$ Sum \propto P D = $6^\circ 35' 47''$ sin. = 9.060224

2) 19.146355

Cos. $\frac{1}{2}$ P A B = $9.573177 = 68^\circ 1' 18''$

2

P A B (the true azimuth, § 291. § c.) = N $136^\circ 2' 32''$ E

B A *n* (the magnetic do. (§ 304. § a.)) = N $119^\circ 25'$ E

N A *n* = Variation (§ 311.) = $16^\circ 37' 32''$ E.

§f. The difference between the true and magnetic azimuths (§ 308. § a.) ($N A B - n A B = N A n$) is the variation. } Plate 2.

§g. The true, being greater than the magnetic azimuth, the variation (§ 311.) is easterly.

§ 323. Bearing in mind, that the co-sec. sine, etc., of an arc (§ 99.), is the sec., cos., etc., of the complement of that arc, the process by which the subjoined formula is deduced from (§ 322. § e.) the one above, becomes manifest.

§ a. Calculation by this formula operates more directly upon the data, and is, perhaps, preferable in practice on account of its greater readiness.

§ b. P.D. = 110°

Alt. = $16^\circ 48' 25''$ sec. = 0.018959

Lat. = 40° sec. = 0.115746

2) $166^\circ 48' 25''$

$\frac{1}{2}$ Sum = $83^\circ 24' 12''$ cos. = 9.060242

($\frac{1}{2}$ S. ∞ P.D.) = $26^\circ 35' 48''$ cos. = 9.951425

2) 19.146372

Cos. $\frac{1}{2}$ tr. azim. = 9.573186 = $68^\circ 1' 15''$

2

Tr. azimuth = N $136^\circ 2' 30''$ E.

§ c. This difference of $2''$ in the result of the two methods, arises from the fraction of a second in $\frac{1}{2}$ sum; which, in either case, is not taken into computation.

§ d. Whence (§ 323.) the rule for calculating an azimuth. Take the difference between the P.D., and $\frac{1}{2}$ sum of the lat. alt. and P.D.; then the product of the cos. of this $\frac{1}{2}$ sum and of this difference, multiplied by the product of the sec. of the lat. and of the alt., is double the cos. of $\frac{1}{2}$ of the true azimuth.

AMPLITUDES.

§ 324. When the magnetic, and true amplitudes of a body, are both north, or both south, the difference between them is the variation.

§ a. But when one of the amplitudes is north and the other south, they are of different names; and their sum is the variation.

§ 325. If the amplitudes be of the same name (§ 324.), and the true be the less northern, or the greater southern amplitude, the variation is easterly when the object is rising; and,

§ a. The variation is also easterly, when the object is setting, and the true is north and the greater, or south and the less, of the two amplitudes.

T

§ 326. If "*magnetic*" be read for "*true*" in the conditions above, the variation becomes westerly.

§ 327. If the amplitudes be of different names (§ 324. § a.), and the *true* be the northern amplitude, when the object is rising, or the southern amplitude when the object is setting, the variation is westerly.

§ a. The converse of these conditions makes the variation easterly.

§ 328. The true amplitude and declination of a body, are always of the same name.

§ a. Therefore it is known by inspecting the declination, whether the true amplitude be north or south.

§ 329. Every object in the heavens, always rises and sets to the north, or to the south of the east and west points, according as its declination is north or south;

§ a. The equator (§ 272. § a.) cuts the horizon in the east and west points; and a parallel of north or south declination, being (§ 257.) parallel to the equator, must therefore cut the horizon, (if at all), to the north or south of the east or west points.

§ 330. A body (say the sun), rises and sets in the points, in which the parallel of its declination cuts the horizon.

Plate 2. { § a. Thus the sun's declination being 20° S., it rises and sets in the points (*c* & *d*) in which the parallel (*d e c*) of that declination cuts the horizon.

§ 331. To an observer who is on the equator, the sun's declination at the time of its rising or setting, is its amplitude; for,

§ a. The equator is then the prime vertical, and that arc of the horizon which (§ 292.) measures the amplitude, coincides with the arc of the circle of right ascension, which (§ 255. § b.) measures the declination.

§ 332. The sun rises in the east, and sets in the west, point, only twice in the year.

§ a. This happens at the moments in which the sun enters the first point of Aries, and the first point of Libra, for (§ 226. and § 226. § c.) the sun is then crossing the equator.

§ 333. To an observer at either pole, the horizon and equator coincide, and the sun does not set, while it is on that side of the equator, which is next to the observer. And,

§ 334. If the observer approach any point of the equator, that point will rise *above*, and the one diametrically opposite, will sink *below*, the horizon as many degrees as the observer advances from the pole. And,

§ a. The observer will not see the sun go below the horizon, until his distance from the pole is greater than the sun's declination.

§ 335. When the latitude and the sun's declination are of the same name, the sun is not seen to set as long as its declination is greater than the co-latitude.

§ 336. To find the sun's true amplitude, and thence the variation.

§ 337. At sun-rise in lat. 40° N., the sun's declination being 20° S., its magnetic amplitude was E. $9^{\circ} 53' 32''$ South; required the true amplitude, and the variation.

§ 338. The place of the sun at the time of its rising (§ 330. § a.) is at the point (*c*) in which the parallel of its declination intersects the horizon; *w A e* (§ 303.) is the magnetic prime vertical; } Plate 2.
the arc *E c* (§ 292.) is the true, and *e c* (§ 305.) the mag- }
netic, amplitude of the sun; and *P A c* is the triangle of the proposed problem, of which the sides are given, and *P A c* is the part required. The triangle (§ 142.) is quadrantal, of which the quadrantal side is *A c*, the zenith distance.

§ a. Now (§ 150. § a.), calling the quadrantal side (*A c*) radius, and the legs (*P A*, *P c*) angles, and the angle *P A c* a leg, the problem is an example under Case IV. (§ 173. § b.).

$$\text{§ b. } P A \text{ or co-lat.} = 50^\circ \text{ cosec.} = 0.115746$$

$$P c \text{ or Z. D.} = 110^\circ \text{ cos.} = 9.534052$$

$$\text{Cos. } P A c = 9.649798 = 116^\circ 31' 4''$$

§ c. Now (§ 133. § a.) the arc *N E c* is the measure of the angle *P A c*; and the arc *E c* (§ 52. § a.) is the complement of *N E c*, and (§ 292.) the sun's true amplitude.

$$\text{§ d. } E c, \text{ the sun's true amplitude} = E 26^\circ 31' 4'' S$$

$$e c, \text{ the sun's magnetic do.} = E 9^\circ 53' 32'' S$$

$$\text{The variation} = 16^\circ 37' 32'' E \text{ (§ 324.)}$$

§ e. The amplitudes are both south, and the true is the greater; wherefore (§ 325.) the variation is easterly.

§ 339. By recurring to § 323. it is evident that the process of calculation (§ 338. § b.) for determining the amplitude, may be simplified, and rendered more convenient in practice, by a similar artifice.

$$\text{§ a. Lat.} = 40^\circ \text{ sec.} = 0.115746$$

$$\text{Dec.} = 20^\circ \text{ sin.} = 9.534052$$

$$\text{Sin. ampl.} = 9.649798 = 26^\circ 31' 4''$$

$$\text{Magnetic ampl.} = 9^\circ 53' 32''$$

$$\text{Variation} = 16^\circ 37' 32'' E$$

§ b. Whence the general rule in practice, for finding an amplitude.

The sine of the amplitude is the *product* of sec. of the lat. and sine of the dec. See Table VII.

SUNRISE.

§ 340. When the latitude of an observer, and the sun's declination, are either both north, or both south, the sun always rises before, and sets after, six o'clock.

§ 341. When the latitude and declination are of different names, the sun rises after, and sets before, six o'clock.

§ 342. When the sun rises in the east, or sets in the west, point of the horizon, the sun is (§ 272. § a.) on the equator, and (§ 263. Plate 2. § a.) in its six o'clock hour circle (W P E); and therefore rises and sets at six o'clock.

§ 343. The time of sunrise subtracted from 12 o'clock, gives the time of sunset, when the points in which the sun rises and sets, are equidistant from the point at which it crossed the meridian.

§ a. This happens when the declination at sunrise, and at sunset, is the same.

§ 344. When the sun (§ 342.) rises and sets at six o'clock, it is also in the first point of Aries, or of Libra;

§ a. As the sun's declination increases, its right ascension (§ 259.) becomes greater, and the first point of Aries farther from the east point of the horizon, when the sun is rising; and,

§ b. The interval between sunrise and 6 o'clock, also increases.

TIME.

§ 345. The time between sunrise and 12 o'clock, in any latitude, may be determined by knowing the sun's declination.

§ a. This operation consists in finding the value of the horary angle A P c, which the circle (P c) of declination, in which the sun rises, makes (§ 263.) with the meridian (N P S) of the place.

§ 346. The value of this angle, (A P c), like that of every other, is expressed in degrees; but may be converted into time, in the proportion of 360° to 24h, which (§ 218. § a.) is the mean time in which the earth performs a diurnal revolution.

§ a. $\frac{360^\circ}{24} = 15^\circ$; therefore the sun describes an horary angle of 15° in 1h; $\frac{1h}{15}$ or $\frac{60m}{15} = 4m$; wherefore the sun describes an horary angle of 1° in 4m, of $15'$ in 1m, and of $15''$ in 1s.

§ b. Whence the rule for converting longitude, degrees, etc., into time, and the reverse.

§ 347. Divide the degrees by 15, for hours, the product of 4 and the remainder, is minutes, (m); the quotient of the minutes (') by 15 is also minutes, (m); and the product of 4 and the remainder to this quotient, is seconds (s); also the quotient of the seconds (") by 15 is seconds (s) of time.

§ 348. The product of hours by 15, and the quotient of the minutes (m) by 4, are degrees; the product of the remainder of the minutes (m) by 15, and the quotient of the seconds (s) by 4, are minutes ('); and the product of the remaining seconds (s) by 15, is seconds (").

§ a. The two first and two last columns of Tables II., show (with the hours at the bottom or top,) the value in time of the degrees and minutes which stand nearest to them.

§ b. And these columns may be used for finding the logarithmic value of hours, minutes, and seconds, as well as for converting de-

degrees, etc., into hours, etc., and vice versa. Therefore in the solution of problems, in which a given or required part consists of hours, etc., these need not be commuted in the process of solution, into degrees, etc.; but may be operated with in calculations, under the denomination of *time*, and thus save the trouble of substituting their value in degrees, etc.

§ c. Substituting hours, etc., for degrees, etc., the logarithmic value of a horary angle may be taken from Tables II., according to the directions given under § 102. for degrees, etc. Thus, to take from the tables the log. of $4h, 20m, 40s$; $4h$ is found at the right hand *bottom* corner of the tables; $20m$ is found in the right hand (*m*) column; and above $20m, 40s$ is found in the (*s*) column on the same side; opposite to $40s$, and in the column which has the required precept at the *bottom*, is the required log.; thus, log. sine $4h 20m 40s = 9.957863$.

§ d. The time corresponding to any log. is taken from the tables according to the directions under § 103. given for taking out the degrees, etc., for a log. sine, etc. Thus, the value in time of log. sin. $9.618004 = 1h 38m 4s$. The log. 9.618004 is found in the column marked (sin.) at the *top*. In the left hand column (*s*) of the page, and opposite to 9.618004 , is $4s$; above $4s$ in the (*m*) column is $38m$, and at the top of the page on the same side is $1h$.

§ e. The small columns marked (diff.) show the difference which $1s.$ or $15''$ make in the log. sine, etc. of an arc or angle.

§ f. To convert $33^\circ 10'$ into hours, etc.; in juxtaposition with 33° is $2h$; and in the left hand columns, $10'$ is opposite to $40s$; and above $40s$, is $12m$; then $33^\circ 10' = 2h 12m 40s$.

§ g. To convert $5h 20m 28s$ into degrees, etc.; $5h$ is found at the bottom, and $20m 28s$ in the right hand columns. In juxtaposition with $5h$ is 80° , and above $20m$, but opposite to $28s$, stands $7'$ in the (*'*) column; then $5h 20m 28s = 80^\circ 7'$.

§ 349. To find the time of sunrise in lat. $40^\circ N.$, the declination being 20° south.

§ a. The triangle of the problem proposed, is the quadrantal triangle $A P c$ with the same data, and a similar } Plate 2.
process, which were used (§ 338. § b.) for finding the amplitude;

$$§ b. P c, \text{ or } P. D. = 110^\circ \cot. = 9.561066$$

$$P A, \text{ or } \text{Co-lat.} = 50^\circ \cot. = 9.923813$$

$$\text{Cos. } A P c \text{ (§ 348. § d.)} = 9.484879 = 4h 48m 52s.$$

§ c. $4h 48m 52s \propto 12h$ (§ 341.) $= 7h 11m 8s$, the apparent time of day at sunrise.

§ d. If the declination were $20^\circ N.$, $4h 48m 52s$ (§ 340.) would be the apparent time of day at sunrise, and $7h 11m 8s$ at sunset,

§ e. The angle $c P E$, (§ 263. § b.) is the complement of the horary angle $A P c$.

§ f. And being the difference between sunrise and 6 o'clock, (§ 262.) it is the ascensional difference.

§ 350. To find the ascensional difference, we have only to take

Plate 2. $\left\{ \begin{array}{l} \text{the sine, where cos. was taken above, in the operation} \\ (\S 349. \S b.) \text{ for finding the time between sunrise and noon.} \end{array} \right.$

§ a. P. Dist. = 110° co-tang. = 9.561066
 Co-lat. = 50° co-tang. = 9.923813

$$\text{Sin. } c P E = 9.484879 = 1h 11m 8s.$$

§ b. 1h 11m 8s (§ 349. § c.) is the complement of 4h 48m 52s, and (§ 349. § f.) is the ascensional difference.

§ 351. By using the trigonometric functions of the complements, the calculation (§ 350. § a.) is rendered more convenient for practice.

§ a. Dec. 20° tang. = 9.561066
 Lat. 40° tang. = 9.923813

$$\text{Sin. } c P E = 9.484879 = 1h 11m 8s.$$

Whence the rule for finding ascensional diff.

§ b. The *product* of the tang. of the lat. and dec., is the sine of the ascensional difference.

§ 352. When the latitude and declination are of the *same* name, the ascensional difference *subtracted* from 6 o'clock, gives the apparent time of day at sunrise; and,

§ 353. *Added* to 6 o'clock, when they are of *different* names, it gives the apparent time of sunrise.

§ a. Hence Table VIII. also shows the apparent time at *sunrise*, when the lat. and dec. are of the *same* name; and the apparent time of *sunset* when the lat. and dec. are of *different* names; for (§ 343.) the time at sunrise subtracted from 12h shows nearly the time at sunset. In the Table, the time from sunrise to 12 o'clock is supposed to be always equal to the time from noon till sunset.

§ 354. The length of the days and nights may be determined by means of the problem (§ 351.); for doubling the time from sunrise till noon, gives the time that the sun remains above the horizon; and,

§ a. Subtracting this time from 24, gives the length of the night, or the time that the sun is below the horizon.

THE PLANETS, MOON, ETC.

§ 355. A satellite is a body that revolves around a planet, as the centre of one of its motions, and also revolves with that planet around the sun.

§ a. The moon is the earth's satellite.

§ 356. Mercury and Venus, (§ 230.) are called *inferior* planets, because their orbits are between the earth's and the sun.

§ 357. Mars, Jupiter, Saturn, Herschel, etc., (§ 230. § a.) are *superior* planets.

§ a. Their orbits are further than the earth's is, from the sun.

§ 358. Jupiter has four satellites, which, revolving with different radii around its centre, accompany it in its revolutions around the sun.

§ a. As they revolve in their orbits from west to east, they pass behind Jupiter; and as they pass in front of it, they cross its disc. From the frequency of these passages, (called eclipses,) and the celerity of the motion of the satellites, their eclipses with Jupiter furnish excellent opportunities for ascertaining longitude, when the observer is on shore. The satellites cannot be seen with the naked eye, and are of no use for ascertaining longitude at sea, because telescopes for observing their immersions and emersions, cannot be used on ship-board on account of the motion of the vessel.

§ b. When Jupiter is nearly in conjunction with the sun, the satellites cannot be seen at all.

§ 359. The moon moves from west to east in its orbit, around the earth.

§ a. The average, or mean time in which the moon performs one revolution in its orbit, is $27d\ 7h\ 43m\ 5s$; this is called a *periodical month*.

§ b. The moon performs, in nearly the same time, one revolution on its axis, by which means the same side of the moon is always presented towards the earth.

§ 360. At the same time every day, the moon is seen about $13^{\circ}\ 10'\ 30''$ further to the east than it was the day preceding.

§ a. This gives the moon an hourly motion with regard to the sun, or fixed stars, of about $32'\ 56''$; and makes the lunar, about $49m$ longer than the solar day.

§ 361. When the moon presents a round, illuminated disc towards the earth, the latter is between the sun and the moon.

§ a. The moon is then about the point in its orbit at which it attains its greatest distance from the sun; and is said to be in *opposition* with the sun.

§ 362. At new moon, the moon is nearest to the sun, being between it and the earth.

§ a. The moon is then in *conjunction* with the sun.

§ b. The interval between two consecutive new or full moons is about $29d\ 12\frac{1}{2}h$.

§ c. This interval of time is called a *synodical month*, to distinguish it from a *periodical month* (§ 359. § a.).

§ d. The difference between the *periodical* and *synodical* months is caused by the motion of the earth in its orbit around the sun; for by the time the moon returns in its orbit to the same place in the heavens, and is again in the position with regard to the fixed stars, which it had occupied $27d\ 7h\ 43m\ 5s$ (§ 359. § a.) before, the earth will have advanced in its own orbit, and the moon will have to continue on in its orbit, about $2d$ and $5h$, before it overtakes the earth, and occupies the position, with regard to the earth and the sun, and presents the same appearance, which it did when the two months commenced together.

§ 363. The light of the moon is reflected from the sun.

§ *a*. And the different appearances of the moon's figure, called *phases*, are caused by the enlightened part of the moon being turned more or less towards the earth.

§ 364. When the moon, passing between the earth and the sun, crosses the straight line which joins their centres, the whole of its unenlightened side is turned towards the earth; then it eclipses the sun, and is seen, like an opaque circular plane, passing over the disc of the sun.

§ 365. If the plane of the moon's orbit coincided with the plane of the ecliptic, the sun would be eclipsed at every new moon.

§ *a*. But as these planes are inclined at an angle of several degrees towards each other, the new moon passes sometimes below, and sometimes above, the line of vision from the earth to the sun.

§ 366. At full moon, when the earth intercepts the line of vision from the sun to the moon, the latter passes into the shadow of the earth caused by the sun, and is eclipsed.

§ *a*. The moon is not eclipsed at every opposition, on account (§ 365. § *a*.) of the inclination of the plane of its orbit to that of the ecliptic.

§ 367. *Syzygies* are the points in which the moon is, (§ 361. § *a*. & § 362. § *a*.), at opposition and conjunction. Consequently, the moon is in syzygy at every new or full moon.

§ 368. An eclipse of the sun or moon takes place only when the moon is in syzygy, and at, or near, one of its nodes (§ 231.).

§ 369. When the moon is half way between the syzygies, it appears as a semicircular plane, with the round part turned towards the sun.

§ *a*. Only half of the enlightened surface of the moon being seen from the earth, produces the appearance of a *half moon*.

§ *b*. In this position, the moon's angular distance from the sun is about 90°, and the moon is said to be in quadrature.

§ 370. A quadrature is marked (\square), opposition (δ), and conjunction (δ).

§ *a*. There are two quadratures; one between new and full moon, the other between full and new moon.

§ 371. *Disc* is the face of the sun, of a planet, or of a satellite.

§ 372. *Digit* is the twelfth part of the breadth of a disc.

§ 373. *Apogee* is that point in the orbit of a body which is furthest from the earth.

§ 374. *Perigee* is that point in which, when a body is, it is nearest to the earth.

§ 375. *Aphelion* and *perihelion* are positions of a body with regard to the sun, similar to those of apogee and perigee with regard to the earth.

§ 376. The motion of light is progressive.

§ *a*. During the time which a ray of light requires to come from the sun to the earth, the latter advances in its orbit nearly 21''; this

causes the sun to be seen about that much always in the rear of its actual position in longitude.

§ 377. The sun's *aberration*, is the difference between the sun's longitude, at the time of the emanation of a ray of light from it, and its longitude, at the time when this ray reaches the earth.

§ a. The amount of aberration must always be added to the sun's *apparent* longitude, in order to obtain the *true* longitude of the sun.

§ b. The longitude of the sun, given in the ephemeris, is *apparent*.

§ 378. *Radius vector* is a line supposed to join the centres of a planet and the sun.

§ a. The logarithm of "the radius vector of the earth" is the logarithmic value of the earth's radius vector; the semi-axis major of the earth's orbit being taken as the base, or unity, in the logarithmic scale.

TIME OF DAY.

§ 379. In the triangle P A B, are comprised the elements necessary to the operation of finding, by trigonometrical calculation, the apparent time of day. } Plate 3.

§ a. B P A, (§ 263.), is an horary angle, and if any three parts of the triangle in which it is, be given, the value of B P A is at once determinable.

§ 381. The primitive data, in the problem for finding the time of day by an observation, are usually the latitude of the observer, and the altitude and declination of the body under observation.

§ a. The complements of which form the triangle (B A P) of the problem.

§ 382. By inspecting the triangle of the problem proposed, it appears evident, that the horary angle (A P B) expresses the interval of time that elapses between the taking of the observation, and the transit of the body, (say the sun), across the meridian of the observer.

§ a. The time thus deduced is *apparent* time.

§ 383. If the observation be made in the forenoon, the value of the horary angle must be subtracted from 12h, in order to find the apparent time of day.

§ a. But if the time be P. M. the value of the horary angle expresses the apparent time of day when the altitude was measured.

§ 384. This problem, coming under Case V., (§ 201.), may be solved by either of the methods of solution there shown.

§ a. But as it is a rule, in the application of theory to practice, (and one too, which is highly important in navigation,) to combine facility of design with readiness of execution, a solution of the problem after the formula, § f. (§ 201.), will be given, in order to show thereby a process of solution less circuitous; by which process the problem under consideration may be solved.

§ 385. In lat. 20° N.; the observed altitude of the sun's lower

limb, was $29^{\circ} 29' 50''$; and its declination was $10^{\circ} 20'$ south. To

Plate 3. { find the time of day, the observation being made P. M.

§ a. First to find the true altitude of the sun's centre.
 § b. Obs. alt. Sun's L. L. = $29^{\circ} 29' 50''$
 Sun's semi-diam. = $15' 47''$

Sun's app. alt. = $29^{\circ} 45' 37''$ (§ 283. § a.)
 Refraction (§ 284.) = $1' 37''$ (Table IX.)
 Dip = $4'$ (§ 275. § a.)
 Sun's true alt. = $29^{\circ} 40'$ (§ 283. § b.)

§ c. To find the time of day.

B A, or Z, Dist. = $60^{\circ} 20'$
 P A, or Co-lat. = $70^{\circ} 00'$ co-sec. = 0.027014 (§ 201. § f.)
 P B, or P. Dist. = $100^{\circ} 20'$ co-sec. = 0.007102

2)230° 40'

$\frac{1}{2}$ sum = $115^{\circ} 20'$ sin. = 9.956089
 ($\frac{1}{2}$ sum ∞ Z. Dist.) = $55^{\circ} 00'$ sin. = 9.913364

2)19.903569

Cos. $\frac{1}{2}$ A P B = 9.951784 = $1h 46m \frac{1}{2}s$

2

Horary angle A P B = 3h 32m 1s

This time (§ 383. § a.) is P. M.

§ 386. The data of the problem may be operated upon, more directly, by using the lat. and alt., instead of their complements.

§ a. Alt. = $29^{\circ} 40'$
 Lat. = $20^{\circ} 00'$ sec. = 0.027014
 P. D. = $100^{\circ} 20'$ co-sec. = 0.007102

2)150° 00'

$\frac{1}{2}$ sum = $75^{\circ} 00'$ cos. = 9.412996
 ($\frac{1}{2}$ sum ∞ Alt.) = $45^{\circ} 20'$ sin. = 9.851997

2)19.299109

Sin. $\frac{1}{2}$ A P B = 9.649554 = $1h 46m \frac{1}{2}s$

2

Horary angle A P B = 3h 32m 1s

§ 387. Whence the general rule for practice.

Take the difference between the true alt., and half the sum of the lat., P. dist., and alt.; then the *product* of the sine of this difference, and cos. of said half sum, *multiplied* by the *product* of sec. of lat., and co-sec. of P. dist., is the sine of half the horary angle.

§ 388. The time thus found being apparent time, may be converted into mean time (§ 217.), by applying to it the equation of time, according to the precept given with the equation of time in the Nautical Almanac.

§ a. App. time (§ 385. § c.) 3h 32m 1s P. M.
Equation of time — 13m 50s

Mean time = 3h 18m 11s

§ 389. By comparing the mean time thus found, with the time shown by a chronometer, or other time-piece, when the altitude was measured, the error of the time-piece is obtained.

§ a. If this time-piece be regulated for a prime meridian, which is the case with chronometers; the difference between the true chronometrical, and the mean, time found by observation, expresses in *time* the difference in longitude between said prime meridian and the place of observation.

§ b. This difference of time being converted (§ 348. § g.) into degrees (°), minutes (′), etc., expresses the longitude of the observer.

LONGITUDE BY CHRONOMETER.

§ 390. The whole doctrine of determining longitude, consists in knowing the time of day at any two places at the same instant.

§ a. This is what is determined by every practicable method of finding longitude; whether it be by means of rockets, eclipses, occultations, lunar observations, or chronometers.

§ 391. The time of day at the prime meridian when an eclipse, occultation, or distance, occurs, is set down in the ephemeris; and the time of day at any other place when the same eclipse, etc., occurs, is known, either by well-regulated time-pieces, or by observations.

§ a. And the difference between these times, (§ 389. § b.), gives the longitude of the observer.

§ b. The longitude is west, when the *prime meridian* (Greenwich, § 252. § c.) time is in advance of the time of day at the observer.

§ c. But if the observer's time of day be in advance of the Greenwich time, his longitude is east; for it is evident that the sun must cross his meridian, before it does that of Greenwich, and consequently, that Greenwich must be to the westward.

§ 392. Chronometers are generally regulated so as to show the mean time of day at Greenwich.

§ a. But they are subject to variations from change of tempera-

ture, etc., and from other causes, and cannot be regulated so as to show at all times, the true time of day at Greenwich, or at any other prime meridian.

§ 393. The difference between the time shown by the face of a chronometer, and the mean time of day at Greenwich, is called "the error of chronometer."

§ *a.* The daily variation of this error is "the rate of chronometer."

§ 394. The rate of chronometer is found by noting the difference between mean time, and the time shown by the face of the chronometer, and after several days, noting again the difference between the mean and the chronometer time.

§ *a.* The difference between these two *differences*, (called "comparisons"), shows the time which the chronometer has gained, or lost, from the first to the last comparison.

§ *b.* And the quotient of this gain or loss, by the number of days that elapsed between the two comparisons, is the daily gain or loss, or rate, of the chronometer.

§ 395. The error (§ 393.) being applied to the chronometer time, with the precept of *plus* or *minus*, according as the chronometer be slow or fast, of Greenwich time, gives the mean time of day at Greenwich.

§ *a.* And the *rate* of the chronometer being applied to the chronometer's error yesterday, with the precept +, or —, according as the *rate* is *increasing* or *decreasing*, gives the chronometer's error for to-day.

§ 396. Before the chronometer is rated, the mean time of day at Greenwich for rating it, is found by turning the longitude of the observer, (§ 347.) into time; and,

§ *a.* Adding this time to the observer's mean time of day, if he be in west long.

§ *b.* And subtracting it from his mean time of day, if he be in east longitude.

§ 397. Ten or twelve days previous to the sailing of the vessel, will generally serve for keeping her chronometer under comparison, in order to find its error, and ascertain its rate.

§ *a.* But after sailing, the rate should be compared, (and corrected if necessary), as often as opportunities for making comparisons occur.

§ 398. To find the error and ascertain the rate of a chronometer, the observer being in lat. $40^{\circ} 42' N.$ and long. $74^{\circ} 00' W.$

§ *a.* Aug. 4th, A. M., 1834.

§ 399. By inspecting the triangle (P B A) of the problem for finding the apparent time of day, it becomes evident, that if, of the lat., time of day, dec., alt., and azimuth, of the sun, or any other body, any three be known, the two others are determinable. } Plate 3.

§ a. The azimuth gives the angle P A B; and the apparent time of day gives the angle A P B; the altitude (B I) determines the zenith distance A B; the latitude A Q, determines P A, the co-lat., and the declination k B, determines the polar distance P B.

LATITUDE BY MERIDIAN ALTITUDES.

§ 400. The most common method of determining latitude at sea, is by means of an altitude of a celestial body, measured when the body is on the meridian.

§ a. Then the circle of the body's declination, coincides with the meridian (N A S) of the observer.

§ 401. Suppose the body be a star; the zenith distance (A e') (§ 282. § b.) expresses the number of degrees, etc., from (A) the zenith to the star.

§ a. And the declination Q e' (§ 255. § b.) gives in the same measure, the distance of the body from the equator.

Plate 3. $\left\{ \begin{array}{l} \S b. \text{ Wherefore the difference between the declination} \\ \text{(Q } e') \text{ and the zenith distance (A } e') \text{ gives A Q the latitude.} \end{array} \right.$

$\S 402.$ The sun being south of the observer, and its declination $10^{\circ} 20'$ south, its meridian altitude (corrected) was $59^{\circ} 40'$.

To find the latitude of the observer,

$\S a.$ The sun's altitude ($\S 282. \S a.$) is $e S$; $90^{\circ} - e S = A e$ ($\S 282. \S b.$) the zenith distance.

$\S b.$ The observer being at A, north of the sun, makes ($\S 281. \S b.$) the zenith dist., A e , north.

$\S c.$ The dec. Q e , being taken from the zenith dist. A e , leaves A Q, the required latitude.

$\S d.$ Sun's Z. D. ($\S a.$) = $30^{\circ} 20' N.$ ($\S b.$)

Sun's dec. = $10^{\circ} 20' S.$

Lat. = $20^{\circ} 00' N.$

$\S 403.$ Suppose the object to bear south, but its dec. to be $9^{\circ} 3' N.$ and its meridian alt. $79^{\circ} 3'$.

To find the latitude,

$\S a.$ The stars alt. is $e' S$; $A S - e' S = A e'$ the *'s zenith dist.

$\S b.$ The dec. Q e' being added to $e' A$ the zenith dist., makes A Q, which is the latitude.

$\S c.$ *'s Z. D. = $10^{\circ} 57' N.$

*'s dec. = $9^{\circ} 3' N.$

Lat. = $20^{\circ} 00' N.$

$\S 404.$ Suppose the star to be north of the observer, its declination $60^{\circ} 5' N.$, and its meridian alt. = $49^{\circ} 55'$.

To find the lat. of the observer,

$\S a.$ N e'' is the *'s alt. The zenith dist. ($\S 281. \S c.$) is south; $NA - N e'' = A e''$, the *'s zenith dist.

$\S b.$ The dec. Q $e'' - A e''$ (the zenith dist.), gives A Q, the lat.

$\S c.$ *'s dec. = $60^{\circ} 5' N.$

*'s Z. D. = $40^{\circ} 5' S.$

Lat. = $20^{\circ} 0' N.$

$\S 405.$ Wherefore, when the dec., and the meridian zenith dist. are both north, or both south, their *sum* is the latitude.

$\S 406.$ And, when one is north, and the other south, their *difference* is the latitude.

$\S 407.$ When the body is in the zenith, there is no zenith dist., and the dec. is the lat.

LATITUDE BY DOUBLE ALTITUDES.

§ 408. The sun, (and every other celestial object), is frequently obscured by clouds, so that a meridian alt. cannot be measured.

§ a. Under such circumstances, data sufficient for determining the lat. may be obtained by taking at two different hours of the day the sun's alt., and noting the time that elapses between the two observations.

§ 409. The time, expressed in degrees, or hours, etc. (§ 348. § b.) constitutes, with the zenith and polar distances, the required data.

§ 410. This method of finding the lat. is called "by *Double Altitudes*."

§ a. The process of calculation is tedious, but the result will give the latitude as correctly as it can be obtained through any other process of observation and calculation.

§ 412. For determining the lat. by "double altitudes," }
 B D represents the declination, and B l the alt. of the sun, } Plate 4.
 at the first observation; and B' D', and B' l' the dec. and alt., at the second observation.

§ a. A P B is the sun's horary angle at the first, and A P B', its horary angle at the second, observation.

§ b. The difference (B' P B) between these two angles, is the angular value of the time that elapses between the observations.

§ c. B B' is the arc of the great circle, which passes through the points, in which the centre of the sun was at each observation.

§ d. The other circles, arcs and angles, of the Fig., are explained under § 317. (§ a.).

§ 413. The problem of "double altitudes" involves three triangles (B' P B, A B B', & A P B') in the process of solution.

§ a. The side B' B is common to the first and second triangles; P B' to the first and third; and A B' to the second and third.

§ 414. The parts that are given in the first triangle (B' P B), are the two sides, P B and P B' (§ 412.), which are the P. dist. (§ 256.) at the first, and the second observation; and (§ 412. § b.) their contained angle B' P B = Elapsed Time.

§ a. And the parts required are, the third side B' B, and the angle P B' B.

§ 415. The value of P B' B and B' B being determined by calculation, the parts that are then known in the second triangle A B B', are B A and B' A (§ 412.); which are the zenith dist. (§ 281.) of the sun at the first and the second observation; and the common side B' B.

§ a. The part here required, is the angle A B' B.

§ 416. The difference between the angles A B' B, and P B' B (§ 414. § a.) gives the value of the angle A B' P, in the third triangle A P B'.

§ 417. Then in the third triangle, the two sides A B', P B' and their contained angle A B' P, are the given parts; and P A is the part required, and the co-lat.

§ 418. In north latitude, at 7 A. M. by a watch.

§ 421. In the example last quoted, the two observations are taken at the same place ; but in practice, this cannot always be done, especially at sea, when the vessel is changing her place during the time that elapses between the taking of the observations.

§ a. Therefore the 1st altitude must be corrected, in order to know what it would have been, had it been taken at the same time per watch, but at the place where the 2d obs. was made.

§ 422. When the first observation is being made, note the bearing of the sun and the course of the ship ; and after the second observation has been taken, find in a traverse table (Table IV.), the

course and distance from the place where the first, to that where the second, observation was taken.

§ a. The angle, which this distance makes with the bearing of the sun, being used in the traverse table, as a course, the correction which is to be applied to the first alt., is found under this course, and opposite to said distance, and in the column marked "*d. lat.*"

§ 423. If this angle be less than 90° , the correction thus found is additive.

§ 424. If it be greater than 90° , its supplement is the course; and,

§ a. The correction is subtractive.

§ 425. If the ship sail on the line of the sun's bearing, the distance sailed in miles, is the correction in minutes ($'$) of a degree.

§ a. It is additive when the ship sails towards the sun; and,

§ b. Subtractive when she sails from the sun.

§ 426. The corrections are found as geographical miles, but are to be applied to the altitude as minutes ($'$) of a degree.

§ 427. When the angle between the bearing of the sun, and the course which the ship makes, is 90° , there is no correction.

§ 428. The corrections thus obtained and applied, do not show *exactly* what the 1st altitude would have been at the place of the second observation; but the approximation is sufficiently close to answer the purposes of common navigation.

§ 429. The time that elapses between the taking of the observations, should not be less than 30*m*, or more than 6*h*, if avoidable, especially if the observer be at sea.

§ a. If the body under observation do not change much in declination during the "elapsed time," the *mean* of its declination at the two observations may be used as the body's declination at each observation.

§ b. This "*mean*" declination is found by taking out the declination for half of the "elapsed time," *plus* the time of the first observation.

Plate 4. } § c. When the *mean* declination is used, $PB = PB'$; and the first triangle $B'PB$ (§ 140.) is isosceles.

§ 430. The latitude at the time and place of the first observation, may be found, if required, by making APB the third triangle, and using the angles PBB' , ABB' and ABP , instead of $PB'B$, $A'B$ and $A'B'P$ (§ 420. § b. & § c.).

§ a. But generally, in navigation, the latitude of the time present, is most desirable to be known; and usually, when the problem is solved, the vessel is nearer to the place of the second, than she is to the place of the first observation.

§ b. A formula for practice in finding the latitude at sea by "double altitudes;" the mean declination being used. Under the example § 418.

Sun's mean dec.	= $22^\circ 24' 30''$,	P. D.	= $67^\circ 35' 30''$
Sun's 1st alt.	= $24^\circ 58' 12''$,	1st Z. D.	= $65^\circ 1' 48''$

2

Lat. = 37° 34' 56'' or co-lat. = 52° 25' 4''

§ d. The result by this method differs 57'' from the truth. Like every other trigonometrical calculation, in which true data are not

operated upon, it brings an error into the result; but the result is an approximation, which oscillates about the truth, and within limits that depend upon the correctness of the assumed data.

§ c. Some navigators solve the problem of "double altitudes" by the method proposed by a Mr. Douwes; but the correctness of the result by his method, depends upon repeated calculations, or the proximity of a *supposed*, to the correct, latitude.*

§ 431. Latitude by "double altitudes" may also be determined by taking, at the same instant, the altitudes of any two bodies, whose right ascension and declination are given.

§ 432. The method of solving this problem consists in a process of operation, precisely similar to that (§ 420.) for finding the latitude by means of two altitudes of the same body, taken at different times.

Plate 4. { § 433. The difference in right ascension of the two bodies gives an angle, which corresponds to the angular value (B' P B) of the "elapsed time," between the two observations.

§ 434. When the difference in right ascension of the two bodies, exceeds 180° or $12h$, the greater right ascension, subtracted from the less *plus* $24h$, gives the angle corresponding to B' P B.

§ 435. In this method of finding latitude, the altitude of the moon, unless the Greenwich time be known, cannot be used with certainty of success. For the moon's variation in declination and right ascension, is so rapid, that unless the Greenwich time of day, when the observations are made, be known, the proper value of the angle corresponding to B' P B, cannot be obtained.

§ 436. The stars afford the greatest facilities for the application of this problem to practice.

§ a. Their variation in declination and right ascension, being for the most part, not very rapid; consequently when the horizon is well defined, the data requisite to the solution of the problem, can be obtained by means of the stars, with sufficient accuracy.

§ 437. In north lat. June 2, 1834, Jupiter being east, and Mars west, of the meridian; their altitudes were taken at the same instant;

 { § 438. B I and B D are Jupiter's altitude and declina-

* Mr. Douwes' method is both supported and questioned by high authority. Bowditch has adopted it in his PRACTICAL NAVIGATOR. And there is a paper from M. Delambre, showing that the result by this method is not always an approximation, but that, in some cases, if repetitions be made, the result will recede from the true latitude.

tion; and $B' P'$, and $B' D'$ are Mars' alt. and dec.; and $B' P B$ } Plate 5.
 is the angular value of their difference in right ascension. }

§ 440. $B P B'$ is the first triangle in the problem, that is brought under calculation; $B' B$ and $B' B P$, are the required parts.

§ a. $B' A B$ is the second triangle, and $A B B'$ is the part in it, that is required;

§ b. $A B B' \propto B' B P = A B P$.

§ c. $A P B$ is the third triangle, and $A P$ is the part required to complete the problem.

- § 441. $P B$ (J.'s P. D.) = $71^\circ 59' 20''$
- $P B'$ (M.'s P. D.) = $84^\circ 5' 40''$
- $B' P B$ (diff. R. A.) = $2h 18m 16s$
- $A B$ (J.'s Z. D.) = $18^\circ 11' 0''$
- $A B'$ (M.'s Z. D.) = $19^\circ 30' 48''$

§ a. To find the value of $B' B$ (§ 200. § s. & § t.)

$B' P B$ (diff. R. A.) $2h 18m 16s$ cos. = 0.915646

$P B$ (J.'s P. D.) = $71^\circ 59' 20''$ tang. = 0.487937

Tang. auxl. $a = 0.403583 = 68^\circ 27' 15''$

M.'s P. D. = $84^\circ 5' 40''$

M.'s P. D. $\propto a = 15^\circ 38' 25''$

$P B$ (J.'s P. D.) = $71^\circ 59' 20''$ cos. = 0.9490243

Auxl. $a = 68^\circ 27' 15''$ sec. = 0.435044

($a \propto P B'$ (M.'s P. D.) = $15^\circ 38' 25''$ cos. = 0.983614

Cos. $B' B = 0.908901 = 35^\circ 49' 42''$

§ b. To find the value of the angle $P B B'$ (§ 420. § b.)

$B B'$ $30^\circ 49' 42''$ co-sec. = 0.232578

$B P B'$ (diff. R. A.) = $7h 18m 16s$ sin. = 0.9753862

$P B'$ (M.'s P. D.) = $84^\circ 5' 40''$ sin. = 0.997689

Sin. $P B B' = 0.984129 = 105^\circ 23' 52''$

Plate 5. | § c. To find the value of A B B' (§ 201. § f.)

$$\begin{aligned} \text{A B' (M.'s Z.D.)} &= 19^\circ 30' 48'' \\ \text{A B (J.'s Z. D.)} &= 18^\circ 11' 00'' \text{ cosec.} = 0.505764 \\ \text{B' B} &= 35^\circ 49' 42'' \text{ " } = 0.232578 \end{aligned}$$

$$\underline{2)73^\circ 31' 30''}$$

$$\begin{aligned} \frac{1}{2} \text{ Sum} &= 36^\circ 45' 45'' \text{ sin.} = 9.777063 \\ (\frac{1}{2} \text{ S } \omega \text{ A B', M.'s Z.D.}) &= 17^\circ 14' 57'' \text{ " } = 9.472066 \end{aligned}$$

§ d. To find the value of A P or co-lat. (§ 200. § u.)

$$\text{A B P} = 85^\circ 58' 52'' \text{ cos.} = 8.845627$$

$$\text{P B} = 71^\circ 59' 20'' \text{ tang.} = 0.487937$$

$$\text{Tang. Auxl. } a = 9.333564 = 12^\circ 9' 52''$$

$$\text{A B (J.'s Z. D.)} = 18^\circ 11' 06''$$

$$\underline{(\alpha \omega \text{ J.'s Z. D.}) = 6^\circ 01' 8''}$$

$$\text{P B (J.'s P. D.)} = 71^\circ 59' 20'' \text{ cos.} = 9.490243$$

$$\text{Auxl. } a = 12^\circ 9' 52'' \text{ sec.} = 0.009864$$

$$\underline{(\alpha \omega \text{ A B, J.'s Z.D.}) = 6^\circ 1' 8'' \text{ cos.} = 9.997599}$$

$$\text{Cos. A P (co-lat.)} = 9.497706 \text{ S.} = \text{lat. } 18^\circ 30' 4'' \text{ N.}$$

§ 442. The data for determining latitude by "double altitudes" may be obtained also by taking the altitude of two objects, each at a different time of the day.

§ a. This method may sometimes be found useful in cloudy weather, when the two objects cannot be seen at the same time, and when it is highly important to know the latitude.

§ 443. When the first object (say a star) is seen, let its altitude be taken, and the time, per watch, when the observation is made, noted down.

§ a. The bearing of the star at the same time, must also be observed, in order that the angle may be known, which is contained between this bearing, and the rhumb line, upon which the ship sails until the second observation may be made.

§ b. This angle, and the distance sailed during the interval that elapses between the taking of the two observations, are to be used

in finding the correction (§ 422. § a.) which must be applied to the first altitude, to make it what it would have been, had it been taken at the place where the second observation was taken.

§ 444. The right ascension and declination of this star must be taken out of the Nautical Almanac, also for the time at which its altitude was measured.

§ 445. When the second object (say the sun) is seen, its altitude also must be taken, and the time of its being done noted down, in order to know the time which has elapsed since the first observation.

§ 446. The right ascension and declination of the sun, when its altitude is measured, must also be found, in order to obtain the difference in right ascension of the two bodies when their altitudes were taken.

§ u. This difference is an angle formed at the pole, by the intersection of the circle of right ascension, in which the star was, when its altitude was taken, with the circle of right ascension which passed through the centre of the sun, when the alt. of it was measured.

§ 447. This angle corresponds to $B'PB$; and with the } Plate 5,
portion of *apparent time* that elapses from the taking of }
the first, till the taking of the last, observation, it constitutes the
angle which is contained between the P. distances of the two bodies;
and with the polar and zenith distances of these bodies, it also con-
stitutes the required data of the problem.

§ 448. The sum or difference of the *difference* of the two bodies in right ascension, and the portion of *mean time* from one observation to the other, give the required contained angle.

§ a. If the sun be the second object, the *apparent* instead of the *mean* time, from one observation to the other, must be taken.

§ 449. The sum of said two quantities is the value of this angle, when the first object is to the eastward of the second.

§ 450. But when the second is the more eastwardly object, the difference of the two in right ascension, *minus* the *elapsed* time, gives the value of the required polar angle.

§ 451. If, when the second is the eastern object, the elapsed time exceed the difference in right ascension of the two bodies, the second will have crossed the hour circle (§ 263. § c.) which coincides with the circle of declination, in which the first object was, when its altitude was measured.

§ 452. The excess of the elapsed time above this differ- } Plate 6.
ence in ascension, is the value of the required polar angle }
($B'PB$).

§ 453. B represents the place of Venus (the first object), when its altitude was taken.

§ a. Venus was then the morning star, and consequently to the westward of the sun, (which is the second object).

§ b. Venus' altitude was taken in the morning, when the sun was below the horizon.

§ c. Pb is an arc of the circle of right ascension in which the sun was, when Venus' altitude was taken.

Plate 6. } § *d*. $B' P b$, is the angular value of the difference in right ascension of the sun and Venus, when the altitude (B) of the latter was taken; it is about $2h\ 36m\ 54s$.

§ 454. The sun's altitude, $B' l'$, was taken $4h\ 29m\ 45s$ after Venus' was measured.

§ 455. The sun had then crossed over the hour circle $P B$ (§ 263. § *c*.) in which Venus was, when its altitude was taken.

§ *a*. The sun was at B' , to the westward of this circle, when its altitude was taken.

§ 456. $B' P b$, is the horary angle, in *apparent* time, which the sun described during the interval between the taking of the altitudes.

§ *a*. Consequently the difference ($B P b$) of the sun and Venus in right ascension, when their altitudes were measured, subtracted from ($B' P b$) the angular value of the *apparent* time between the observations, gives the value of the angle $B' P B$.

§ 457. If the portion of time that elapses, between the observations, be given in mean time, it may be converted into apparent time, by applying to it the fraction which during the elapsed time, the second object's equation of time gains or loses, on mean time.

§ 458. In surveying expeditions the elapsed time should be corrected and changed into *apparent* time, in order to determine the latitude with exactness.

§ 459. But upon the open sea, this nicety in operation may be omitted, for it only advances, by a very small fraction, the accuracy of the result.

§ 460. If the altitude of the more easterly object, be taken last, and the elapsed time be equal to their difference in right ascension, the same hour circle (§ 263. § *c*.) will pass through each object when its altitude is taken; and the process of deducing the latitude will be confined to the simple operation of finding an angle with the three sides of a triangle as data; and thence in deducing, from the two sides and their contained angle, as data in a second triangle, its third side, which is the co-lat.

§ *a*. The three sides of the former of these two triangles, would be the zenith dist. of each body, and the difference between their polar distances.

§ 461. Feb. 25, 1832. Venus being the morning star, and the observer being in south latitude when he made his observations.

§ *a*. Venus' Alt. $24^{\circ}\ 50'$ (*True*.)
 " Dec. $20^{\circ}\ 5'$ S.
 " Rt. Ascen. $19h\ 59m$
 " bearing $E. \frac{1}{4} S.$ (§ 443. § *a*.)

Time per watch $3h\ 16m\ 19s$

§ *b*. The ship then sailed N. E. $\frac{1}{4}$ N. 18 miles, when the sun was seen, and its altitude taken.

Sun's Alt. $43^{\circ}\ 44'$ (*Correct*. § 385. § *b*.)
 Sun's Dec. $9^{\circ}\ 16'$ S.
 Sun's Rt. A. $22h\ 30m\ 59s$
 Time per watch $7h\ 46m\ 8s$

§ 462. The angle between the bearing of Venus (§ 461. § a.), and the ship's course, is five points, which (§ 422. § a.) with the distance sailed, (18 miles), gives 10' (§ 426.) in the column (*d. lat.*) of the traverse tables; which 10' (§ 423.) being added to Venus' altitude, makes it 25°, (what it was at the time of its being taken, but at the place where the sun's alt. was observed.)

§ 463. The watch kept *mean* time. The elapsed time (§ 457.) must therefore be corrected, in order to obtain the portion of *apparent* time, that elapsed from the first, until the second observation was taken.

§ a. During this interval there were 2s less of apparent, than of mean time, which being subtracted from the mean time elapsed, gives the elapsed apparent time.

§ 464. This correction is obtained from the ephemeris. It is the quantity which the equation of time gains or loses from the first to the second observation; and it must be applied accordingly.

§ 465. The triangulation, through which the process } Plate 6.
of finding the latitude by means of the data in this pro- }
blem is conducted, is represented in the triangles B' P B, A B' B and A B' P.

$$\begin{aligned} \text{§ 466. } AB (\text{star's Z. D.}) &= 65^\circ 0' \\ PB (\text{star's P. D.}) &= 69^\circ 55' \\ AB' (\text{sun's Z. D.}) &= 46^\circ 16' \\ PB' (\text{sun's P. D.}) &= 80^\circ 44' \\ \text{Elapsed mean time} &= 4h 29m 49s \\ \text{Correction (§ 463. § a.)} & \quad \quad \quad 2s \end{aligned}$$

$$\begin{aligned} \text{Elapsed app. time} & \quad \quad \quad = 4h 29m 47s \\ \text{Diff. in R. A. of sun and star} &= 2h 31m 59s \end{aligned}$$

$$B' P B = 1h 57m 48s \quad (\text{§ 456. § a.})$$

To find the latitude.

§ a. In the triangle B' B P, to find the value of B' B. (§ 200. § n.)

$$\begin{aligned} B' P B = 1h 57m 48s \quad \cos. &= 9.939911 \\ P B' (\text{Sun's P.D.}) = 80^\circ 44' \quad \text{tang.} &= 0.787389 \end{aligned}$$

$$\text{Tang. auxl. } a = 0.727300 = 79^\circ 23' 15''$$

$$PB = 69^\circ 55' 0''$$

$$\text{Sin. Complement } A P, \text{ or lat.} = 9.736688 = 33^\circ 2' 59'' \text{ South.}^*$$

* This differs 1'' from the truth.

LUNARS.

§ 467. The problem of finding the *true* distance between the sun, or a star, and the moon, for the purpose of thence determining the longitude, is one of great importance in navigation.

§ 468. The necessity for the circuitry of calculation in finding the longitude by lunar observations, arises from the circumstance that the two observed bodies are not seen (§ 289.) in their true places.

§ *a.* They always appear, each in its proper azimuth circle, but higher up, or lower down in it (§ 283. § *c.*), than its true place,

§ *b.* And consequently (§ 283.) they appear either nearer to, or farther from, each other, than they really are, which makes the difference between the true, and apparent lunar distance.

§ 469. Only two triangles are involved in the process of finding, by trigonometrical calculation, the *true* from the *observed* lunar distance.

§ *a.* Of the first triangle, the three sides are given; and the angle required is that which is contained at the zenith, between the zenith distance of the moon, and of the other body.

§ *b.* Of the second triangle, this angle and its adjacent sides, are the given parts; and the third side, or true lunar distance, is the part required.

§ *c.* The three sides of the first triangle are the apparent lunar, and the app. zenith distances of the two bodies.

§ *d.* And the three sides of the second triangle, are the *true* lunar and zenith distances.

§ 470. The *lunar*, or the *true lunar distance* of the sun, or a star, is an arc of a great circle, contained between the centres of either of those objects, and the moon.

§ 471. The distance between the perfect limb (§ 283.), or the round edge, of the moon and the near limb of the sun, is the distance usually measured with a sextant.

§ 472. The *apparent* is obtained from the observed distance, by applying, with proper signs, the corrections for the error of the sextant, for the semidiameters of the two bodies, and for the augmentation of the moon's semidiameter.

§ *a.* The sun and moon's semidiameter is given in the ephemeris; the sun's for every 24*h*, and the moon's for every noon and midnight.

§ *b.* The correction for augmentation is found in Table X.

§ 473. *Augmentation* of the moon's semidiameter, is the difference between the visual angle of the moon's semidiameter at the centre, and its visual angle at the circumference, of the earth.

§ 474. The difference between these two angles, is proportional to the ratio between the length of the semidiameter of the earth, and its distance from the moon.

§ 475. On account of its great distance from the earth, the sun's semidiameter has no augmentation.

§ *a.* As the earth's semidiameter measures more in proportion to

the moon's geocentric distance, than to that distance of the sun, or of any other heavenly body, the difference of the moon's semidiameter, when seen from the circumference and from the centre of the earth, is greater than that of any other body, when seen from the same positions.

§ 476. The semidiameter of the moon when it is in the horizon, appears under nearly the same visual angle (barring refraction) that it does from the centre of the earth.

§ 477. The moon appears larger when it is in the horizon, than it does when in the zenith. This though is an optical delusion, for the moon actually subtends the largest visual angle when in the zenith; as it is then nearer to the observer than it is when in the horizon, by a little more than the semidiameter of the earth.

Plate 7. } § 478. $B' A B$ represents a diagram of the lunar problem.
 $b' b$ is the apparent, (§ 472.), and $B' B$ the true (§ 470.) lunar distance.

§ 479. The three apparent distances, ($b' b$, $b' A$, $A b$), are the given parts (§ 469. § α .) of the first triangle $b' A b$, and the angle $b' A b$ is the part required in it.

§ 480. The angle $b' A b$ is common to the second triangle $B' A B$, of which the true zenith distances $A B$, and $A B'$ are the given, and the true lunar distance $B' B$ is the required part.

§ 481. The apparent Z. D. of the sun, or of a star, (§ 284. § α .) being less, and the app. Z. D. of the moon (§ 286. § α .) being greater, than the true Z. D.; it appears from the diagram, that, when the moon's is the greater of the two Z. D., the true is always less than the apparent lunar distance.

§ α . And when the moon's is the less Z. D., the true is sometimes greater, and sometimes less, than the app. distance.

§ b . The true is the less, when the lunar distance exceeds 90° .

§ c . And it is generally the greater, when the distance is less than a quadrant, and the ratio of cos. moon's Z. D. to cos. sun or star's Z. D., is greater than the ratio of rad. to cos. of the lunar distance.

§ 482. The reason why the difference between the app. and the true L. dist., appears to be governed by the moon more than by the other body, is, that the moon being nearer to the earth, has the greater parallax, and is generally seen further from its true place in the heavens, than any other body, from which lunar distances are measured, appears from its true place.

* The *dip*, when the eye is 9 feet above the water, is about 3'; and 4', when the height of the eye is 17 feet. On board ship 4' is generally allowed for *dip*.

† When the nicest accuracy is required, corrections may be applied for the difference in the effects of refraction on the upper and the lower limb of the sun and moon; for the moon's parallax in different latitudes, supposing the equatorial to be greater than the polar diameter; and also a correction for the actual barometrical, and thermometrical state of the atmosphere; but at sea, greater errors are unavoidable, hence these corrections are of minor importance.

$$\begin{array}{r}

 \hline
 \end{array}$$

§ 484. By referring to the Nautical Almanac, page xvli., of the ephemeris for Aug. 1834, it will be observed, that it was near noon of the 27th at the Greenwich observatory, when the moon was $89^\circ 53' 24''$ from the sun.

§ a. If the latitude of the place at which the observation (§ 483.) was made, be known, the time of day at that place, and when the observation was taken, may be found according to the rule § 387.

§ b. And the difference (§ 391. § a.) between the time of day thus found, and the time in the ephemeris, which corresponds to the calculated lunar distance, is the longitude in time.

§ 485. Distances for determining longitude are always measured from the moon, because the change of the moon's position in the heavens is more obvious than that of any other heavenly body that is visible to the naked eye.

§ 486. The moon (§ 360.) has a daily motion of about $13^\circ 10'$ in the heavens; owing to which the moon rises, culminates, and sets, later and later every day, until, having passed through all its phases, it crosses the circle of the sun's altitude, gets to the eastward of the sun, and presents the appearance of a new moon.

§ 487. At a mean, an error of $2' 12''$ in the lunar distance, will produce an error of 1° in the longitude.

§ 488. The moon changes its distance from those bodies, which lie directly in its path, more rapidly than it does from those towards or from which it moves more obliquely.

§ a. Therefore the stars from which the change of the lunar distance for the time being is the most obvious, should be preferred in taking lunar observations; for the more rapidly the distance changes, the less will the longitude be affected by a small error in the observation.

§ 489. In the Nautical Almanac; pages xliii. to xviii., of the ephemeris for each month, contain at intervals of three hours, the distance of the moon from the sun, from four of the planets, and eight of the principal fixed stars.

§ a. The small column, marked P. L. contains the proportional

logarithm of the quantity, which the distance preceding it in the left hand column, varies during the three hours between which the P. log. stands.

§ b. Table III. of this volume, contains the proportional log. for every second from 1" to 3°; or for every second of time from 1s to 3h.

§ c. Proportional logarithms are nothing more than the *difference* between the log. of 3, and the log. of the given number less than 3.

Thus, the log. of 3	-		=0.4771+
Log. of 12'; (12' reduced to the decimal of a degree is 0.20.)		Log. 0.20	9.8010+

$$\text{P. log. of } 12', \text{ or } 12m = \underline{\underline{1.1761}}$$

§ d. This Table (III.) is always used for finding the Greenwich time when a given lunar distance occurred.

Thus, to find the time at Greenwich when the sun was distant from the moon			
84° 17' 10"	Diff.	-	20' 51" P. L.=9362
L. Dist. at 6. 83° 56' 19"			Diff. for 3h=1° 20' 9" P. L.=3514
" at 9. 85° 18' 28"			
			46m 49s=5848

And 46m 49s added to 6h, shows the time (6h 46m 49s) at Greenwich, when the sun was distant from the moon 84° 17' 10".

§ e. This is a much shorter way than that of arriving at the same result by common logs.; thus,

As 1° 20' 9"=1.336 (decim'ls of a deg.)	Ar. co.=9.874193
Is to 3h	Log. =0.477121
So is 20' 51"=0.3475 (do. of a deg.)	Log. =9.540955 (§ 90.)

To 46m 49s=0.7803	" "	Log. = <u>9.892269</u> (§ 93. § g.)
-------------------	-----	-------------------------------------

§ 490. In selecting a star to measure a lunar distance from, that one should be fixed upon, whose lunar distance at the time has the *least* p. log. after it in the ephemeris; for, as the greatest variations in the dist. are represented by the smallest p. logs., the lunar dist. of those bodies, which has the smallest p. log. after it, is increasing or decreasing, in a greater ratio, than that is which has after it a greater p. log.; consequently, (§ 488. § a.) those bodies are the most favourably situated for determining longitude.

§ 491. When practicable, the distance of the moon should be measured from two stars; one to the east, the other to the west of it; and the *mean* of the longitude resulting from the observations should be taken as the long. of the place.

§ a. If the sextant have an unknown error, the error will partially

Z

correct itself by its own counteracting effects in distances measured to the east and west of the moon.

§ 492. Latitude by "double altitudes" may also be determined by means of the data in the lunar problem.

Plate 7. { 493. By inspecting the lunar diagram, it is seen that the arcs (P B, P B') of the circles of declination of the sun and moon, join the extremities of the true lunar distance (B' B), forming thereby the triangle B' P B, of which the three sides are known.

§ a. Then the value of the angles P B B', and A B B' being found, their difference gives the value of A B P, which, with B A, and B P in the triangle P A B, constitutes data requisite for determining A P, the co-latitude.

§ 494. The lunar problem is one of the most useful and most beautiful problems in navigation; for besides his longitude and latitude, the navigator may deduce, from the principles involved in it, data for the solution of almost any problem in nautical astronomy.

§ 495. The three parts A P, P A B, A P B, in the fourth triangle, are determinable from the data obtained by a lunar observation.

§ a. A P is the co-lat. of the place of observation.

§ b. A P B is the horary angle, which (§ 382. § a.) shows the app. time of day at the place of observation when the latter was made. And,

§ c. The difference between this time converted into *mean* time, and the Greenwich time in the N. A. that corresponds to the lunar dist., expresses, in time, the longitude of the place of observation.

§ d. P A B is the sun's true azimuth at the time and place of observation; the difference between it, and the sun's magnetic azimuth, (§ 308. § a.) is the variation of the compass.

§ 496. By increasing the triangulation, and extending the operations, other *quæsitæ* may be added to the problem; and the length of the day and night; the time of the sun and moon's rising and setting; the hour of the moon's passing the meridian; the hour when each object bears east or west; the duration of twilight; and the amplitudes of the two objects on the day, and at the place of observation, may all be determined by means of the parts involved in the common lunar problem.

§ 497. Therefore when, on account of unknown drifts, and of gales during several days in succession of thick or cloudy weather, a ship has lost her reckoning, it may be successfully restored by a single lunar observation.

§ a. If the variation of the compass be required also at the same time in addition to the lat., time of day, and longitude, the calculation, after being conducted into the fourth triangle B A P, should be conducted by a process different from that for evolving the value of A P, the co-lat., alone.

§ b. In the latter case, the value of A P would be determined by the rule § s. and § t., under Case IV. (§ 200.)

§ c. And in the former case, the proportion between the sines of opposite sides and angles, would evolve it; for, when the three un-

Plate 7. $\left\{ \begin{array}{l} \text{known parts of this triangle (B A P) are required, the} \\ \text{most direct method of arriving at the required results,} \end{array} \right.$
 consists in applying the rules § z. and § z a., Case IV., (§ 200.) to calculation, in order to determine first the value of the horary and azimuth angles (A P B, & P A B.)

§ d. In trigonometrical operations, that method of calculation should ever be adopted, which, being less elaborate, arrives more directly at the required result.

§ 498. When the latitude, etc., is required by means of a lunar observation, the operation of correcting altitudes and of finding the true lunar distance, is conducted as it is under § 483. ; and then the value of A B B' is found, before the operation passes from the second triangle B' A B.

§ a. The true lunar distance B' B being determined, the Greenwich time corresponding thereto, is found (§ 489. § d.) in the lunar tables of the Ephemeris; and then the declination and the right ascension of the sun and moon, at this time, are found in the appropriate tables of the Nautical Almanac.

§ 499. The declination of the two bodies thus found, gives (§ 258. § b.) the sides B' P and B P.

§ a. And the difference of their right ascensions (§ 433.), expresses in time the value of the angle B' P B.

§ b. The angle P B B' is the only part in this triangle, which is required, and it may be found without the trouble of taking from the Ephemeris, the right ascension of the two bodies.

§ 500. The true lunar distance (§ 483.) $89^{\circ} 53' 24''$ of the problem occurred (§ 484.) at Greenwich, August 27, 1834, near mean noon, when the sun's declination (page ii. of the Monthly Ephemeris) was $10^{\circ} 10' 2''$ N.; and the moon's (page v. to xii. do.) was $19^{\circ} 12' 39''$ N. Their difference in right ascension then was $6h 13m 52s$.

§ a. And the sun's magnetic azimuth (§ 304. § a.) at the time of observation, was N. $109^{\circ} 4' 30''$ East.

§ 501. The apparent and true zenith distances are found, and the calculation for determining the true lunar distance (B' B) is conducted precisely in the same manner, as it is (§ 483.) when the true distance is the only object of the problem.

§ 502. In the second triangle B' A B, to find the value of A B B'.

B' B (Tr. lunar D.)	= $89^{\circ} 53' 24''$ cosec. = 0.000001
B' A B	= $163^{\circ} 15' 8''$ sin. = 9.459632
B' A (Moon's Z. D.)	= $35^{\circ} 19' 12''$ sin. = 9.762035

Sin. A B B' = 9.221668 = $9^{\circ} 35' 24''$

Plate 7. $\left\{ \begin{array}{l} \S a. \text{ In the third triangle } B' P B, \text{ to find the value of} \\ P B B'. \end{array} \right.$
 $B' B$ (Tr. L. D.) = $89^\circ 53' 24''$ cosec. = 0.000001
 $B' P B$ (Diff. R. A.) = $6h 13m 52s$ sin. = 9.999205
 $B' P$ (Moon's P.D.) = $70^\circ 47' 21''$ sin. = 9.975116

$$\text{Sin. } P B B' = 9.974322 = 70^\circ 29' 27''$$

$$A B B' = 9^\circ 35' 24''^A$$

$$A B P = 60^\circ 54' 3''$$

$\S b.$ To find, in the fourth triangle, the sun's azimuth $P A B$, and the horary angle $A P B$ ($\S 200.$ $\S z b.$)

$$\frac{AB + BP}{2} = 67^\circ 46' 55'' \quad \text{sec.} = 0.422357 \quad \text{cosec.} = 0.033505$$

$$\frac{AB \oslash BP}{2} = 12^\circ 3' 3'' \quad \text{cos.} = 9.990322 \quad \text{sin.} = 9.319687$$

§ 503. If the latitude and time of day, without the variation, be required from a lunar observation, the process of calculation may be varied from that above for finding the azimuth, time, and latitude; and may be made more direct.

§ a. But in either case, the order and method of calculation are the same, in the process of arriving at the value of A B P in the fourth triangle.

§ 504. The true lunar distance (B' B) must always be determined, before the correct P. distances, (P B, P B') and the difference (B' P B) in right ascension (§ 498. § a.) of the two bodies, can be known.

§ a. These parts must always be taken from the Ephemeris, and for the time in it, which corresponds to the true lunar distance.

§ 505. Having found, in the second triangle, the required angle A B B'; then having taken (§ 498. § a.) from the Ephemeris, the proper P. D., etc., and calculated (§ 502. § a.) the value of the angle (P B B') required in the third triangle; the value of A B P is obtained, and the lat. and time of day may thence be deduced by the following formula.

§ 506. Formula of calculation for finding the latitude and time of day by a lunar observation.

To find the lat. (§ 200. § n.)

	Contd. Angle (A B P) cos. = *.*****	
Sun's Z. D. (A B) cos. = *.*****		tang. = *.*****
Auxl. a	sec. = *.*****	Tang. auxl. a = *.*****

§ 507. If the second and third triangles fall on opposite sides of the lunar distance B' B, then the sum of the angles (A B B' & P B B') of the second and third triangles, gives the value of the required angle (P B A) of the fourth triangle. } Plate 8.

§ 508. When the polar distance of each body is greater than the co-latitude of the observer, then the second and third triangles fall upon the same side of the lunar distance B' B, } Plate 7.

Plate 7. } and the difference between the angles (A B B', P B B') is
 } the value of the angle (A B P) sought in the fourth triangle.

§ 509. It may always be known, whether the sum or difference of the angles of the second and third triangle, will give the angle required to be known in the fourth triangle, by observing the inclination of the plane in which the sextant is held to bring the sun and moon in contact.

§ a. If the sextant be inclined to the plane of the horizon, towards the pole of the observer, then his co-lat. is greater than the P. dist. of either body, and the second and third triangles fall upon different sides of the lunar distance, and the sum of the two angles is the required angle of the fourth triangle.

§ 511. Examples under § 483. and § 510. are drawn out in the solution, in order to familiarize the problem to the student. But such a process of calculation as is there shown, is not desirable in practice; especially that part of it which has been made to come under Case IV., (§ 200. § n.) on account of the perplexity in determining whether the value of the auxl. α be greater or less than 90°.

§ a. Therefore, in practice, those methods of calculation are generally preferred, which give the trigonometric function of *half* the value of the required part; such as § a. (§ 386.), for *half* the value of a required arc or angle should never exceed 90°.

§ 512. The learner has now become familiar with the triangulation, which is brought under calculation in the process of finding longitude, etc., from a lunar observation; he will therefore readily comprehend the manner by which such an operation is simplified, and reduced to the following methods and formulæ for practice.

§ 513. The process of correcting the obs. distance and altitudes is fully shown under § 483. and § 510. This part of the operation

is the same in every method for calculating the true from an obs. lunar distance.

§ 514. An improved method for finding the true from an observed lunar dist.*

§ a. Aug. 27th, 1834.

App. dist. sun & moon = $88^{\circ} 26' 52''$

Sun's app. alt. - $47^{\circ} 52' 12''$

Greenwich time = 4h 25m 42s P. M.

LATITUDE BY THE NORTH STAR.

§ 515. In northern latitudes, the latitude may be found at any time of the night, by an altitude of the north star.

§ 516. If the north star were situated in the pole of the world, its altitude would always show the elevation of the north pole; and (§ 251. § a.) consequently to the observer, his latitude.

§ 517. But as this star revolves in a very small circle around the pole, the elevation of the pole may always be determined by applying to the star's altitude at any time, the corrections opposite to that time in the subjoined tables (A & B).

§ 518. The corrections in Table A, and those after (*'s alt. +) in the hour columns of Table B, are *always* to be added to the star's alt. They are expressed in seconds (").

§ 519. And the other corrections in Table B, must be applied to the star's altitude, according to the precept, which is at the head of the hour column in which the *sidereal* time is found.

§ 520. To find the lat. by an alt. of the north star; the altitude being corrected for dip, refraction, etc.

§ a. Subtract 1' from the star's alt.

§ b. For the supposed time of night when the observation is made, take the corresponding sidereal time; the correction found in Table B and opposite to this time, being applied, according to the precept (§ 519.) at the head of its column, to the star's alt., gives the approximate latitude.

§ c. And the corrections under the hour in Table B, and opposite the hour, but under the "approximate latitude," in Table A, being added to the approximate latitude, give the lat. of the observer.

§ 521. May 4, 1834, long. 85° W. the altitude of the north star, at 7h P. M., was $35^{\circ} 29' 43''$. To find the lat.

TIDES.

§ 525. The flux and reflux of the waters, known under the name of **TIDES**, are caused by the attractive forces of the sun and moon exerted upon the ocean.

§ 526. The moon being nearer to the earth than the sun is, has a greater effect than the sun upon the tides.

§ a. The action of the moon upon the tides, is about three times greater than that of the sun.

§ 527. When the attractive forces of the sun and moon act in conjunction, they produce the highest tides.

§ a. When this is the case, the moon (§ 367.) is in syzygy.

§ b. And the tides caused about this time are called *spring* tides.

§ 528. The tides have the least rise and fall, when the attractive forces act perpendicularly to each other.

§ a. And this is the case, when the moon (§ 369. § b.) is in quadrature. Then the tides are called *neap* tides.

§ 529. That portion of the ocean which is immediately under, and nearest to, the sun or moon, is more attracted by either than the centre of the earth is. This portion then, has a tendency to approach the attracting body, and rises up, until its tendency is counteracted by the attraction of gravitation towards the centre of the earth.

§ a. About twelve hours afterwards, this portion of the ocean, owing to the earth's diurnal motion (§ 206. § a.), is at the furthest point from the sun or moon; and the waters about it, owing to their tendency to restore the equilibrium, which is disturbed by the effects of the attraction of the sun or moon on the opposite side of the earth, rise up and make high tide again.

§ b. Hence, during the time in which the moon is performing one revolution around the earth (§ 362. § d.), the tide rises twice, and falls twice, at the same place.

§ 530. The attractive forces of the sun and moon upon equal portions of the surface of the sea, being (§ 526. § a.) about 3 to 1 in favour of the latter; if the solar tide at any place be 2 feet and the lunar 6, and the moon be in syzygy, the two tides will happen at the same time, and (§ 527. § b.) make a spring tide of 8 feet.

§ a. Then, as the lunar (§ 360. § a.) is longer than a solar day, the following solar will happen earlier than the succeeding lunar tide, by the difference between half a solar and half a lunar day.

§ b. Thus, the lunar tide continues to retard upon the solar tide, until the moon quadrates; when the high lunar and low solar tides coincide in time, and (§ 528. § a.) we have a neap tide of four feet rise.

§ c. After this, the lunar still continues to retard upon the solar tide, until the moon arrives in the other syzygy; when the two high tides again happen at the same time, and bring about other spring tides.

§ *d.* At this second spring tide, the moon has completed half of a revolution in its orbit, and has lost one tide upon the sun; therefore, while the moon is completing one entire revolution through its phases, there are two more solar, than lunar, tides.

§ 531. The attraction of the moon being more partial, and its effect upon small portions of the earth's surface being more obvious than that of the sun, the combined tides are governed more by the moon than by the sun.

§ 532. The effects of the moon's attraction upon the earth, tend (§ 529.) to create high tide, both in that part of the ocean immediately under, and nearest to, the moon, and in that part diametrically opposite; and were not the motion of the waters resisted and obstructed, there would be high tide at the moment when the moon crosses either the superior or the inferior meridian.

§ *a.* But, at some places, the passage of the moon across the meridian, precedes, by several hours, the time of high water.

§ *b.* This retardation of the tides might be explained, by attributing the retarding power to the effects of the resistance, which the shores, unequal depths of ocean, etc., offer to the mass of moving waters, were it not, that the waters do not rise up into spring tides, when the moon is in syzygy, and when the attractive forces of the sun and moon are combined in their action upon the waters; but the highest tides in every synodical month (§ 362. § *c.*), is generally about the third tide after the passage of the moon through either syzygy.

§ *c.* And the least neap tide, is generally the third tide after the moon quadrates.

§ 533. Observations show, that the tides require a little longer time to ebb, than they do to flow.

§ *a.* This difference observable at sea, becomes more obvious in rivers of strong currents.

§ 534. Upon the smaller seas, and sheets of water, such as the Lakes, the Mediterranean, etc., the effect of the lunar and solar attractions, are partially counteracted by the circumscribed limits to their action; and hence but little, or no tide is produced there.

§ 335. There are a variety of causes, (and some of a local nature), which, acting together, tend, some to retard at one place, and others to hasten at another place, the hour of high tide on the full and change days of the moon; so that, there are no general rules for determining beyond certain limits of approximation, the time of high or low water at any place.

§ 536. The greatest interval between two consecutive tides, generally happens about a day and a half after the moon has quadrated; when the tides, (§ 532. § *c.*) being at the minimum of their rise and fall, are the weakest.

§ *a.* And the least retardation of one tide after another, is the 2d upon the 3d, or the 3d upon the 4th tide, after the moon's latest passage through a syzygy; the tides, having then (§ 532. § *b.*) the greatest rise and fall, are strongest.

§ 537. On an average, the tides rise and fall once, in about 12 $\frac{1}{2}$ 48m.

· § a. Consequently every tide retards, at a mean, about 24m, upon the one which it succeeds; and each tide happens about 48m later than it did the day before.

§ 538. Were there not so wide a difference in the tides, between the minimum and maximum of their retardation, the hour of high or low water, at any place and on any day, might be found by adding to the time of high water on full or change days, the product of 48m, and the number of days from the latest full or new moon, to the day proposed.

§ a. About the time of neap tides, there is sometimes a difference of more than an hour and three quarters in the time of high water, on two successive days.

§ b. And a similar difference about the time of spring tides, is frequently less than half an hour.

§ 539. The annexed table (C) shows the retardation of the *mean* tides, upon the hour of high tide on full and change days, for every day between the full and change of the moon.

§ a. Therefore, to find the time of mean high water on any day, we have only to look in the Nautical Almanac (page xii. M. Ephemeris), for the day of the latest new, or full moon, in order to find its age (in days) since the last change in syzygy; the time, in the annexed table (C), found opposite to this age, and added to the time of high water at the place proposed, on full and change days, gives the time of mean high tide for the day when it is so required.

§ b. The hour of high tide at any port, on full and change days, is called the *establishment* of the port.^a

§ c. And the *establishment of the port* for any one place is always the same; for on every full and change day throughout the year, high tides are considered to take place there at the same hour of the day.

§ 540. A table for finding the time of high or low water, at any place, the establishment of the port (§ 539. § b.) being known.

§ a. To find the time of high water at Charleston, Aug. 29, 1834. The establishment of the port being 7h 5m.

§ b. The last change in syzygy (§ 367.) was full moon, Aug. 18th, 20h (N. A., p. 12, M. E.); consequently the moon's age is 10 days.

§ c. Opposite to 10d, and in the column, from \circ to \bullet , is 8h 10m, which, added to the establishment of the port, gives 15h 25m, the hour of high water on the day proposed.

§ d. To find the time of high water at Portland, Feb. 14, 1834; the establishment of the port being 10h 45m

§ e. The last change in syzygy was new moon February 3; consequently the age of the moon is six days.

§ f. Opposite to 6d, and in the column, from \bullet to \circ , is 4h 3m, which, added to 10h 45m, gives 14h 48m, the time of high water.

§ 541. This method does not show the precise hour of high water; but it approximates the true time of high water, within limits which will serve on all ordinary occasions.

§ a. The time of low water may be found by adding 6h 15m to the time of high water on the day proposed.

* The arguments \bullet to \circ , mean from *New* to *Full* moon; and \circ to \bullet , from *Full* to *New* moon.

NAVIGATION.

NAVIGATION.

§ 542. The geographical situation of places, is designated by their distance, north or south, from the equator; and by their distance, east or west, from a prime meridian (§ 252. § c.).

§ a. These distances (§ 248. § b. & § 252.) are known by the name of Latitude and Longitude of the places.

§ 543. It has been shown in Nautical Astronomy, how the latitude and longitude of places may be determined by means of observations made upon the sun, moon, or stars; but in practice these means are not always at hand.

§ a. It remains then to be shown, how the geographical position of places may be determined, by knowing in certain respects, their relative situation with regard to each other.

§ 544. Washington city is to the southward and westward of Baltimore. The difference of latitude between them (§ 254. § c.) is the meridional arc, which is contained between Baltimore and the parallel of the latitude of Washington.

§ a. And the arc of this parallel which is between Washington and the meridian of Baltimore, (§ 254. § b.), is the difference in longitude between the two places.

§ b. These two arcs are perpendicular to each other; for the meridian of Baltimore (§ 248. § a.) cuts the equator at right angles, and the parallel of Washington (§ 249.) is parallel to the equator.

§ c. Now, if a line (W B) be drawn direct from Washington to Baltimore, it will connect their difference of longitude (W L) and of latitude (B L), and form a right angled triangle (W L B), of which the hypotenuse (W B) is the distance, and the legs, the difference of latitude and of longitude, between Washington and Baltimore.

§ d. The two acute angles (W & B) show the bearings of each place from the other. The angle W is the course from Washington to Baltimore, and the angle B is the course from Baltimore to Washington.

§ e. Hence if, of the Dist., Diff. Lat., Diff. Long., and Course, between two places, any two be given, the others are determinable.

§ 545. Now, the section of a loxodromic curve, which a ship traces while she is sailing upon a given course, is the hypotenuse of a right angled triangle, and corresponds to W B.

§ a. Then if the course and distance, which a ship sails in any given time, be known, we have the hypotenuse and an acute angle of a right angled triangle, given; and the other parts are determinable.

§ b. Therefore, knowing the latitude and longitude of the place from which a ship takes her departure, and knowing the course and distance which she sails from that place, in a specified time, we may determine by right angled trigonometrical calculations, the latitude and longitude of the ship, at the end of that time.

§ 546. The sides of all such triangles are curved lines; for the earth (§ 204.) is a spheroid, therefore all triangles upon its surface are spherical triangles, and are properly subject to the rules of spherical trigonometry, for investigation.

§ a. But the laborious operations of obtaining results from these triangles, when brought under calculation, as spherical triangles, would be inconvenient in practice; and they are not necessary in the ordinary purposes of navigation.

§ b. Therefore all such triangles are considered in navigation as right angled plane triangles, and are brought under calculation according to the rules of plane trigonometry.

§ 547. A degree ($^{\circ}$) of all great circles, such as the equator, meridians of longitude, etc., whose radii and the earth's semidiameter are the same, consists of 60 *nautical miles*, or of about $69\frac{1}{2}$ statute miles; so that, calling the number of minutes ($'$), miles, which is contained in an arc of one of these great circles, we have the value of this arc considered as a straight line.

§ a. Wherefore, knowing the distance and the difference of latitude between any two places, the difference of longitude between them, may be determined also in *nautical miles*, by right angled, plane trigonometrical calculations founded upon § 75.

§ b. The difference of longitude thus found, is called departure.

§ 548. *Departure* is the difference in longitude between any two places, expressed in *miles*.

§ a. And the departure in any latitude, may be converted into its corresponding minutes ($'$) of longitude by means of the principles established under § 76.

§ 549. It is evident, that, if in mathematical calculations, curved lines be treated as right lines, there must be an error in the result; and this error increases with the number of degrees contained in such curved lines.

§ 550. The result then, obtained by calculating the sides of a spherical triangle, as though they were the straight lines of a plane triangle, is only an approximation; and the smaller the sides, the closer is the approximation.

§ a. This method therefore is particularly applicable in small distances, and short runs; it is used for working up "dead reckoning", and for calculating the distance, the difference of latitude and

of longitude, and the course, from one place to another; any two of which four quantities being known, (§ 544. § e.), the others are determinable.

§ 551. The diagram shows by a mere inspection, the } Plate 1.
solution of every problem which can occur in right angled }
plane trigonometry, provided the hypotenuse of the triangle involved, do not exceed 300 miles, or 300 units of any measure.

§ a. This diagram may answer the purpose of Tables IV. & V.; and it also shows the principles upon which they are constructed; for the number in the Dist. column of these tables, is the length of the hypotenuse of a right angled triangle, whose acute angles contain, one the number of degrees at the top, and the other those at the bottom of the page, and the value of whose legs is set down opposite to that of the hypotenuse, and in the columns marked Dep. and D. Lat.

§ 552. This diagram, then, shows the solution of every case, or problem in loxodromic sailing; for it shows the dimensions of the triangle involved in every problem, provided the distance or hypotenuse do not exceed 300 miles.

§ a. If it exceed 300 miles, the solution may be obtained by dividing the given side or sides, by 2 or 3, or by any other divisor, which will reduce the triangle of the problem within the limits of the diagram; then the value of the side or sides, obtained, by using said quotient in the diagram, being multiplied by the same divisor (§ 70.), gives the value of the required side or sides.

§ 553. The angle B A D is 45° .

§ a. The acute angles of a right angled triangle (§ 32. § d.) being complementary to each other, the less must always be located at A.

§ b. And the leg adjacent to it, must be called the *base*, and be a part of A D.

§ c. And the leg opposite to it, must be called the *perpendicular*.

§ d. All the straight lines standing upon A D, are alluded to as *perpendiculars*.

§ e. B C is the greatest *perpendicular* in the diagram. Equal portions of it are transferred by means of the parallels *b d*, to the graduated arc B D, for admeasurement.

§ f. The graduated arc B D is thus made to answer the purpose of a graduated *perpendicular*, for the arc contains the same divisions which the *perpendicular* B C would have shown, had it been graduated to the scale of A B and A D.

§ g. The height of every *perpendicular* is therefore shown on that portion of the graduated arc, which is between the *base* (§ b.) and that parallel, under which the *perpendicular* stands. Thus the height of the *perpendicular* *b C*, transferred by the parallel *b d*, to the graduated arc, is $D d = 11.3$.

§ 554. The arcs in the diagram show the angular value of any course, provided it be not more than 4 Points, or 45° .

§ a. If the course be greater than this, they show the angular value of its complement.

§ b. The arcs, 3, 4, 5, etc., also show the length of the *base* and

Plate 1. } hypotenuse of the triangle proposed; while the scale on
 } the graduated arc (§ 553. § g.) shows the value of the *per-*
pendicular ($b c$) in the several triangles.

§ c. The section of any arc, which is contained between the *base*, and the lines $A e$, shows the angular value of the courses which are marked *upon* these lines; and the angular value of the complements (§ 553. § a.) of the courses, marked *under* these lines.

§ d. The marks on the arcs show the value of these arcs in degrees.

§ e. The even numbers (2° , 4° , 6° , etc.) of degrees are marked on the concave side of the arcs; and the odd numbers (1° , 3° , 5° , etc.) are marked on the convex side.

§ f. The degrees (46° , 47° , 48° , etc.) that stand on the outside of the graduated arc, are the complements of those (42° , 43° , 44° , etc.) on the inside of the arc.

§ g. The entire length of every arc (§ 553.) is 45° .

§ 555. The dotted lines, $A e'$, represent quarters of Points; the broken lines $A e$, represent halves of Points; and the continuous lines $A e$ whole Points.

§ a. The distance on a given course is shown on the lines $A e$, at the end of which lines that course is found; then the portion of that line ($A e$) which is contained between A , and the arc 3, 4, etc., which is marked with the distance proposed, is hypotenuse to the triangle required.

§ b. Thus 24 miles on a $2\frac{1}{4}$ Point course, is the distance $A b$ on the broken line $A e$, at the end of which $2\frac{1}{4}$ is marked; and $A C b$ is the right angled triangle, of which the course and the distance proposed constitute an angle and the hypotenuse.

§ c. The two legs of this triangle are the *base* $A C$, and the *perpendicular* $b C$ which stands under the parallel $b d$.

§ d. The graduated scale on $A D$ shows the value of $A C=21.1$, the *D. lat.*; and the portion ($D d$) of the scale on the graduated arc, between the *base* and the parallel $b d$ (§ 553. § g.), shows the height of the *perpendicular* $b C=11.3$, the *Dep.*

§ 556. Now as the distance which a ship may sail upon any loxodromic course, is considered (§ 546. § b.) as the hypotenuse of a right angled plane triangle, if the distance sailed upon such course can be found in the diagram, the departure and difference of latitude, which correspond to that course and distance, may be found by means of the graduated *base* and arc, $A D$ and $B D$.

§ a. Or, if any two of these quantities; viz., Course, Dist., Dep., and Diff. Lat., be known, the other two are determinable by means of the diagram.

§ 557. A ship sails N. W. $\frac{1}{4}$ N. 19 miles, What departure and difference of latitude does she make?

§ a. The given course is found *upon* the dotted line $A e'$, and that portion ($A b$) of this line, which is between A and the 19th arc, is the hypotenuse of the triangle ($A c b$) involved.

§ b. The *perpendicular* ($b c$) intersects the *base* at 14.1, which is the difference of latitude.

§ c. And the parallel, from the top of the *perpendicular*, } intersects the graduated arc at 12.7, which is the departure. } Plate 1.

§ 558. A ship sails N. W. by N. and makes 12.7 miles of departure, What distance and diff. lat. does she make?

§ a. The parallel from 12.7 on the graduated arc, intersects the N. W. by N. line, in the point, (nearly), where the 23d arc crosses it; then nearly 23 (22.9) miles in the distance sailed.

§ b. And the *perpendicular* from this point of intersection, falls upon the *base*, and shows the difference of latitude required, to be 19.1 miles.

§ 559. A ship sails N. by W. $\frac{1}{2}$ W. and makes 19.8 miles diff. lat., What departure and distance does she make?

§ a. The *perpendicular* at 19.8 on the *base*, being traced up, is found to intersect the N. by W. $\frac{1}{2}$ W. line on the 21st arc; then 21 miles is the distance sailed.

§ b. And the parallel from this point of intersection, being traced to the graduated arc, shows the height of the perpendicular 7 miles, which is the departure required.

§ 560. A ship, after sailing 18 miles, finds that she has made 16.2 miles diff. lat., What course did she sail, and what departure has she made?

§ a. The *perpendicular* from 16.2 on the *base*, intersects the 18th arc on the dotted line marked $2\frac{1}{2}$ Points, which is the course required.

§ b. And the parallel from this point of intersection, shows, on the graduated arc, the height of the perpendicular to be 7.8 miles, which is the departure required.

§ 561. A ship sails 28 miles, and finds that she has made 15.6 miles departure, What course and diff. lat. has she made?

§ a. The parallel from 15.6 on the graduated arc, cuts the 28th arc, on the line marked 3 Points, which is the course sailed.

§ b. And the *perpendicular* from this point of intersection, falls upon the *base* at 23.3 miles, which is the diff. lat. required.

§ 562. The departure between two places is 8.7 miles, and the diff. lat. between them is 28.6 miles, What is the course, and the distance from one place to the other?

§ a. The *perpendicular* from 28.6 on the *base*, intersects the 30th arc on the broken line, $1\frac{1}{2}$, which shows the required course and distance to be $1\frac{1}{2}$ Points, and 30 miles.

§ 563. If the distance sailed be not more than a mile, or if the hypotenuse of the triangle proposed, be not greater than 3, the divisions on the scales must be decimated; then the figures 1, 2, 3, 4, 5, etc., stand for $\frac{1}{10}$, $\frac{2}{10}$, $\frac{3}{10}$, $\frac{4}{10}$, $\frac{5}{10}$, etc., and the subdivisions stand for 100ths.

§ a. Wherefore, when the distance is not more than 3 miles, the distance from A, to the 10th arc, is 1 mile; to the 20th, 2 miles; and to the 30th, 3 miles; and all the numbers in the diagram stand for 10ths.

§ 564. What departure and difference of the lat. would a ship make by sailing 2 miles N. W. $\frac{1}{2}$ N.?

Plate 1. } § a. The parallel and *perpendicular* which would pass through the point in which the 20th arc intersects the N. W. $\frac{1}{2}$ N. line, measured by the eye, would cut the graduated arc and base in 12.7 and 15.4.

§ b. And using only one decimal place (§ 563.), the nearest would be 1.5 diff. lat. and 1.3 departure; but the exact is 1.54 and 1.27 diff. lat. and dep.

§ 565. When the lines in the diagram do not pass through the point required by the conditions of the triangle involved, the imaginary lines required, may be traced by the eye with all the precision which is necessary; and after a little practice, with the utmost accuracy and facility.

§ a. Thus, the distance of one place from another, is N. by W. $27\frac{1}{2}$ miles; the triangle involved in this problem, being filled up by the eye, the imaginary parallel and *perpendicular*, cut the graduated arc and *base* in 5.3 and 27; which shows the departure between the two places to be 5.3 miles, and the diff. lat. 27 miles.

§ 566. If the distance sailed on a single course exceed 30 miles, or the hypotenuse of the triangle involved, be greater than 30, all the numbers in the diagram must be increased tenfold.

§ a. Then the arcs must be reckoned as being 10 miles a part; the numbers 1, 2, 3, 4, 5, etc., will stand for 10, 20, 30, 40, 50, etc.; and the distance between these numbers being divided, every one in 10 equal parts, every one of these subdivisions must be counted as 1 mile.

§ 567. A ship sails N. W. 240 miles; what departure and diff. lat. does she make?

§ a. The parallel and *perpendicular* from the intersection of the 24th arc (now counted (§ 566) 240), with the N. W. line, cuts the graduated arc and *base* (§ 41.) at equal distances, and the departure and diff. lat. (§ 14.) are the same.

§ b. Departure = 169.5. diff. lat. = 169.5. This is $\frac{2}{5}$ of a mile less than the result by logarithmic calculation. This difference is owing to the smallness of the scale upon which the diagram is projected, and not to any defect in the principles involved in the projection of the diagram.

§ 568. In the examples quoted above, the courses are *on* the lines, and the diff. lat., except (§ 567.) when the course consists of 4 Points, is always greater than the departure.

§ 569. The courses and figures *under* the lines, (§ 554. § e.) are the complements of those *on* the line above them; and when the course is found *under* the line, the departure is the longest leg of the triangle involved, and must be read off upon the *base* A D; and the diff. lat. is taken from the graduated arc B D.

§ a. A ship sails E. $\frac{1}{2}$ N. 28 miles. What departure and diff. lat. does she make?

§ b. The parallel and *perpendicular* which pass through the point where the 28th arc cuts the dotted line, *under* which the given course is marked, meet the graduated arc and base in 1.3 and 27.9+.

§ c. Then (§ 569.) the departure = 27.9. and the diff. lat. = 1.3.

§ 570. The four cardinal points of the horizon (§ 272.) } Plate 1.
 divide it into four quadrants, each containing 8 Points.

§ a. Wherefore a Point = $11^{\circ} 15'$, the quotient of 90° by 8.

§ 571. The Points, when expressed by numbers, begin at the north and south, and are reckoned in numerical order, to the east and west points.

§ a. Hence, it is easy to conceive that a vessel that sails N. 3 Points W., or N. W. by N., would make more *northing* than *westing*, and that her diff. lat. would be greater than her departure.

§ b. And conversely, that if a vessel sail on any course between 4 and 8 Points, e. g., N. 5 Points W., or N. W. by W., she would make more *westing* than *northing*, and that consequently her departure would be greater than her diff. lat.

§ 572. From what has already been advanced in explanation of the diagram, it appears that the triangle involved in the trigonometrical solution of any problem in *loxodromic* sailing, is a right angled plane triangle.

§ a. *Loxodromic* sailing,* is so called from the sort of curve which the track of a ship forms, when she is sailing upon any course not exactly due east or west, north or south.

§ b. *Loxodromic* curves are spirals, which continually approach the poles, but can never reach them.

§ c. And any course, not due east or west, north or south, is called a *loxodromic* course.†

§ 573. A number of formulæ, varied in the trigonometric functions to be used, may be drawn up for the solutions of the several cases in *loxodromic* sailing.

§ a. The terms in these formulæ depend upon the side of the triangle, whether it be the distance, the departure, or diff. lat., which is made radius.

§ 574. Baltimore is 35 miles N. N. E. $\frac{1}{4}$ E. from Washington. The formula for finding by calculation the departure and diff. lat. between the two places, depends upon the trigonometrical construction which is given to the triangle involved.

§ a. If the hypotenuse be made radius, to an arc B C, the dep. becomes (§ 54.) sine to the course, and the diff. lat. its co-sine.

§ b. Then, (§ 75.), rad. : dist. :: sin. of course : dep. :: cos. course : diff. lat.

* The subdivisions of the *sailings*, viz., Plane, Traverse, Parallel, and Middle Latitude Sailing, are not here preserved. These distinctions are by no means necessary for the purpose of facilitating the navigator's calculations; they have therefore been generalized under the term of *loxodromic sailing*.

† E. by N. is a *loxodromic* course. Suppose a vessel could sail E. by N.

§ c. Hence (§ 74.) are deduced the following formulæ; the three first being the given terms, and the fourth, the unknown and required term, of the proportion.

§ d. Sin. course : dep. : : rad. : dist. (§ 75. § b.).

§ e. Dist. : rad. : : dep. : sin. course.

§ f. Cos. course : diff. lat. : : rad. : dist.

§ g. Dist. : rad. : : diff. lat. : : cos. course.

§ h. Cos. course : diff. lat. : : sin. course : dep.

§ i. Dist. = 35. log. = - - - 1.544068
Course = 2½ pts. (§ 571.) sin. (Table D) = 9.711049

Log. dep. = 1.255117 = 18 miles.

§ j. Dist. 35. log. = - - - 1.544068
Course, 2½ pts. cos. = - - - 9.933350

Log. diff. lat. = 1.477418 = 30 miles.

§ 575. If the triangle be constructed upon the diff. lat. as radius of the arc A E, then the dist. becomes (§ 57.) secant, and the dep. (§ 56.) tangent, to the course.

§ a. And (§ 75.) sec. course : dist. : : rad. : diff. lat. : : tang. course : dep.

§ b. Wherefore, the diff. lat. being taken as radius, the following formulæ are derived either (§ 75. § c.) immediately from the construction of the triangle, or (§ 67. § e.) from the relation of the terms, as they are expressed in the proportion § a.

§ c. Diff. lat. : rad. : : dist. : sec. course.

§ d. Rad. : diff. lat. : : sec. course : dist.

§ e. Diff. lat. : rad. : : dep. : tang. course.

§ f. Tang. course : dep. : : rad. : diff. lat.

§ g. Tang. course : dep. : : sec. course : dist.

§ h. Course 2½ pts. cos. = 9.933350 (§ 101. § b.)
Dist. 35 miles, log. = 1.544068

Log. diff. lat. = 1.477418 = 30 miles.

§ i. Course 2½ pts. cos. = 9.933350
Dist. 35 miles, log. = 1.544068
Course 2½ pts. tang. = 9.777700

Log. dep. = 1.255118 = 18 miles.

without any obstruction, or without ever deviating from that course; the N. pole would then be always *one Point* forward of her beam. It is difficult to imagine how a vessel could ever arrive at such a point.

§ 576. Or if the triangle be constructed upon the dep., as radius of the arc A F, the dist. becomes secant, and the diff. lat. the tangent, of B, the complement (§ 32. § d.) of the course.

§ a. Wherefore (§ 75. § c.) co-sec. course : dist. :: rad. : dep. :: co-tang. course : diff. lat.

§ b. Other formulæ of proportion, similar to those under § 575., might be drawn out here, but these for the most part would be a repetition of those, as the expression 4×6 is a repetition of the form 6×4 of multiplication. Indeed several sets of the proportions under § 574. & § 575., are similar repetitions of each other.

§ c. Course $2\frac{1}{2}$ pts. $\sin.$ = 9.711049 (§ 101. § b.)
 Dist. 35 miles, $\log.$ = 1.544068

$$\text{Log. dep.} = 1.255117 = 18 \text{ miles.}$$

§ d. Course $2\frac{1}{2}$ pts. $\sin.$ = 9.711049
 Dist. 35 miles, $\log.$ = 1.544068
 Course $2\frac{1}{2}$ pts. co-tang. = 0.222300

$$\text{Log. diff. lat.} = 1.477417 = 30 \text{ miles.}$$

§ 577. The principles of the above trigonometrical construction are also developed in the solution of problems } Plate 1.
 by the diagram.

§ a. Thus, to find the course and dist. which correspond to 12 miles diff. lat., and 5 miles dep.

§ b. The perpendicular which cuts the base in 12, is tangent to the 12th arc, and A 12 is its radius.

§ c. The parallel from 5, on the graduated arc, cuts this perpendicular on the 13th arc, at its intersection with the 2 Point line, and A 13 is secant to the course (2 Points) and the dist. required.

§ d. If the dist. A 13, on the 2 Point line be called radius of the 13th arc, then the portion of the perpendicular, between the point of this intersection, is sine of the course, and A 12 on the base, is its co-sine.

§ 578. Table of log. sines, etc., of the Points of the Compass.

§ 579. In every case, except when the dep. and diff. lat. constitute the two given parts, the solution of the problem proposed, may be obtained by means of the proportion (§ 74.) between the sides of a triangle and sines of their opposite angles.

§ a. In the triangle A B C (§ 74.) right angled at B, (§ 74.) dist. : sin. B=90° :: dep. : sin. course; but the sine of 90 (§ 62.) is radius, wherefore we have again the formula § e., (§ 574.), viz., dist. : rad. :: dep.

: sin. course, and a repetition of others under § 574.

§ 580. Some one of the following formulæ (rejecting or borrowing 10 for rad., (§ 197. § f.), in the index of the second member of the equation), may be used in every case where two of the four quantities, dist., course, dep. and diff. lat., are given.

§ a. Dep. (§ 574. § b.)=dist. × sin. course.

§ b. Dep. (§ 575. § e.)=diff. lat. × tang. course.

§ c. Diff. lat. (§ 574. § j.)=dist. × cos. course.

§ d. Diff. lat. (§ 575. § f.)= $\frac{\text{Dep.}}{\text{tang. course}}$ (§ 101. § b.)=dep. × cot.

course.

§ e. Dist. (§ 575. § d.) = diff. lat. \times sec. course.

§ f. Dist. (§ 576. § a.) = dep. \times co-sec. course.

§ g. Sin. course (§ 574. § e.) = $\frac{\text{Dep.}}{\text{dist.}}$

§ h. Cos. course (§ 574. § g.) = $\frac{\text{Diff. lat.}}{\text{dist.}}$

§ i. Tang. course (§ 575. § e.) = $\frac{\text{Dep.}}{\text{diff. lat.}}$

§ j. These formulæ will always be found convenient in practice.

OF TURNING DEPARTURE INTO DIFF. LONG.

§ 581. If the difference of longitude between two places (§ 548.) be expressed in miles, it is called departure.

§ a. A minute of longitude is no where, except at the equator, equal to a mile of departure; for the distance between any two meridians of longitude (§ 248. § a.) is greatest at the equator, and the least about the poles.

§ b. Therefore the dep. between any two meridians is greater at the equator than in any latitude.

§ c. Furthermore, as all meridians (§ 248. § a.) intersect at the poles, the dep. between any two becomes less and less, as you approach the poles, where there can be no dep.; whereas the difference of longitude, between these meridians in any latitude, (§ 254. § a.) is the same, being expressed by the same number of degrees (°), minutes (′), etc.

§ 582. Suppose two places to be situated in the same latitude, the arc of this parallel of latitude, contained between them, (§ 254. § b.) is their difference in longitude.

§ a. And parallels of latitude (§ 249.) are small circles.

§ b. Suppose also an arc of a great circle (§ 122.) to be drawn from one of these places to the other, this arc (§ 122. § a.) would be the shortest distance between the two places, and the minutes (′) contained in it, would show (§ 547.) the departure between them.*

§ 583. These two arcs are contained between the same two points, and (§ 76.) the arcs are to each other, as the radius of the great circle is to the radius of the small circle.

§ a. The rad. of such a great circle, as well as of the equator, etc., (§ 122.) is semidiameter to the earth.

§ b. And the radius of the small circle, or the parallel, (§ 130. § a.) is the cos. of its latitude.

§ 584. Then, calling the semidiameter of the earth, unity, or rad., we have (§ 76.) for any latitude, diff. long. : dep. : : rad. : cos. lat.

§ a. Also cos. lat. : dep. : : rad. : diff. long.

§ b. And rad. : diff. long. : : cos. lat. : dep.

* Hence it appears that the *course* between two places, is never the shortest distance between them, unless they be either upon the equator, or upon the same meridian.

§ c. Wherefore, if any two of these three quantities, (rad. is always known), be given, the other and remaining one is determinable.

§ 585. The terms of these proportions represent quantities, comprised in the elements of a right angled plane triangle.

§ a. Wherefore, if the figure which furnishes such proportions, be considered a plane triangle; it will be right angled, the latitude will be one of its acute angles; the diff. long., the hypotenuse; and the dep. will be one of the legs of such triangle.

§ b. The result obtained from calculations conducted upon such principles, (§ 549.) must be only an approximation.

§ 586. Suppose a ship sailed E. $15\frac{1}{2}$ miles on the parallel of $56^{\circ} 15'$ south latitude, her departure would be $15\frac{1}{2}$ miles, the distance sailed.

§ a. And in the right angled triangle ABC, the angle $A = 56^{\circ} 15'$, the lat.; the leg $AB = 15\frac{1}{2}$, the dep.; and the hypotenuse (§ 585. § a.) is the diff. long.

§ b. Now, if the diff. long. be made radius, of the arc CE; CB becomes its sine, and AB its co-sine, whence (§ 75.) arise the proportions, under § 584.

§ c. Rad. : diff. long. : : cos. lat. : dep.

§ d. Diff. long. : rad. : : dep. : cos. lat.

§ e. Cos. lat. : dep. : : rad. : diff. long.

§ f. To find the corresponding diff. long. by calculation (§ e.).

Lat. $56^{\circ} 15'$ sec. = 0.255261 (§ 101. § b.)

Dep. 15.5 log. = 1.190332

Log. diff. long. = 1.445593 = 27.9 minutes (')

§ 587. If the dep. (AB) be made radius, to the arc BH, then the diff. long. becomes secant to the lat., and we have (§ 75. § c.)

§ a. Rad. : dep. : : sec. lat. : diff. long.

§ b. Sec. lat. : diff. long. : : rad. : dep.

§ c. Dep. : rad. : : diff. long. : sec. lat.

§ 588. Now, if the other leg (CB) be made radius, the dep. becomes co-tang. (§ 57. § b.), and the diff. long. the co-sec., of the latitude, whence (§ 75.) arise the following sets of proportions.

§ a. Co-tang. lat. : dep. : : co-sec. lat. : diff. long.

§ b. Co-sec. lat. : diff. long. : co-tang. lat. : dep.

§ 589. To find the number of miles, or the dep., which correspond to 1° or 60' on the parallel of 67° 30'.

§ a. The diff. long. being made radius, we have, (§ 586. § c.),
 Rad. : diff. long. :: cos. lat. : dep.

$$\begin{aligned} \text{Diff. long. } 60 \text{ log.} &= 1.778151 \\ \text{Lat. } 67^\circ 30' \text{ cos.} &= 9.582840 \end{aligned}$$

$$\text{Log. dep.} = \underline{\underline{1.360991}} = 22.9$$

§ 590. C (§ 32. § d.) is the complement of A, and is equal to 22° 30'. C B is the cos. of C, and shows the number of miles contained in 1° of long. on the parallel of lat. 22° 30'.

$$\begin{aligned} \text{§ a. Diff. long. } 60 \text{ log.} &= 1.778151 \text{ (§ 589. § a.)} \\ \text{Lat. } 22^\circ 30' \text{ cos.} &= 9.965615 \end{aligned}$$

$$\text{Log. dep.} = \underline{\underline{1.743766}} = 55.4 \text{ miles,}$$

which is equal to 1° of long. in lat. 22° 30'.

§ b. Now (§ 75. § b.) $CB : \cos. C :: AB : \cos. A$. AB shows the number of miles equal to 1° of long. in lat. 67° 30', and CB shows the number of miles, that make 1° of long. in lat. 22° 30', the complement of 67° 30'.

§ c. Wherefore, in any lat., the miles in a degree of long. are to the cos. of that lat., as the miles contained by a deg. of long. in any other lat., are to the cos. of this lat. And alternately.

§ 591. As a right angled plane triangle (§ 585,) is in- } Plate 1.
 volved in the solution of the several problems under § 586. }
 § 587. § 588., etc.; the solution of every one of such problems may be obtained by means of the diagram.

§ a. The diff. long. (§ 585. § a.) is the hypotenuse; and the leg adjacent to the angle which in degrees (°), is equal to the latitude in which the dep. or diff. long. is made, is the dep.

§ 592. Of dep., diff. long. and lat., either is determined on the diagram, by means of the two others, in the same manner, that any

D D

Plate 1. } one of the three quantities, viz., diff. lat., dist. and course,
 } is determined (§ 556. § a.) by means of any two of these.

§ 593. When the latitude in which the diff. long. or dep. is made, is less than 45° , the degrees of lat. are to be found on the *inside* of the graduated arc; and the dep. on the *base*.

§ a. But when the latitude is *greater* than 45° , the degrees of it are to be found on the *outside*, and the dep. on, the graduated *arc*.

§ b. Thus, 26' of long. is equal to 24.5 miles, in lat. 19° ; and in lat. 71° , it is equal to 8.4 miles.

§ c. The *perpendicular* from the mark for the 19° th on the 26th arc, cuts the *base* at 24.5, which shows the dep. for 26' of long. in lat. 19° .

§ d. The parallel from 71° on the 26th arc, cuts the graduated arc at 8.4, which is the dep. (§ 593. § a.) for 26' of long. in lat. 71° .

§ 594. A ship in lat. 27° , makes 20.5 miles dep. To find the diff. long.

§ a. The diff. lat. is found on the *inside* (§ 593.) of the graduated arc, and the dep. on the *base*.

§ b. The *perpendicular* from 20.5 on the *base*, intersects 27° on the 23d arc, then 23' is the required diff. long.

§ 595. A ship in lat. 60° , makes 12 miles dep. To find the diff. long.

§ a. The degrees of the lat. (§ 593. § a.) are found on the *outside*, and the dep. on the graduated arc.

§ b. The parallel from 12, intersects 60° on the 24th arc; 24' is the diff. long.

§ 596. The diff. long. between two places in lat. 33° is 27'. To find the dist. between them.

§ a. The lat. is found on the *inside* (§ 593.) of the graduated arc, and the dep. on the *base*.

§ b. The *perpendicular* from 33° on the 27th arc, falls upon the *base* at 22.6, the dist. in miles between the two places.

§ 597. The diff. long. between two places in lat. 54° , is 24'. To find the dist. between them.

§ a. The degrees of lat. are on the *outside*, and the dist. (§ 593. § a.) is to be found on the graduated arc.

§ b. The parallel from 54° on the 24th arc, cuts the graduated arc at 14.1, the dist. required.

§ 598. The dep. between two places on the same parallel, is 18.4 miles, and the diff. long. is 20'. To find their lat.

§ a. The *perpendicular* from 18.4 cuts the 20th arc at 23° , the lat. required.

§ b. The dep. being found on the *base*, the degrees (§ 593. § a.) are taken from the *inside* of the arc.

§ c. But if the dep. were found on the graduated arc, then the degrees on the *outside* of the arc, would show the lat.

§ 599. The diff. long. being 20', and the dep. between two places in the same latitude being 6.8 miles; to find their lat.

§ *e.* The parallel from 7.8, cuts the 20th arc at 67°, { Plate 1.
which (§ 598. § *c.*) is the lat.

§ *b.* When the minutes (') of long. exceed 30', every division on the several graduated scales, (§ 566.) must be counted as a mile, or as a minute (').

§ *c.* And when the minutes (') of long. do not exceed 3', the divisions on the graduated scales (§ 563.) must be decimated.

§ 600. Of the diff. long., dep. and lat., either one may be found, the others being given, by means of Table V.

§ *a.* The degrees at the top of the table, are those which are *inside* of the arc; and those at the bottom of the table, and on the *outside* of the arc, are the same.

§ *b.* The numbers in the column marked (dist.) stand for minutes (') of longitude; they show the value of the hypothenuse of a triangle, whose legs are equal to the quantities in the next two columns; and whose acute angles contain, one the degrees at the *top*, and the other those at the *bottom* of the page.

§ *c.* When the lat. is found at the top of the page, the miles which are equal to any number of minutes of longitude, are opposite to them in the column marked, at the top, (d. lat.)

§ *d.* Thus, in lat. 41°, 60' of long. = 45.3 miles.

§ *e.* If the degrees of lat. be found at the bottom of the page, then the miles which are equal to any number of minutes (') of long., are found opposite to them in the column marked (d. lat.), at the bottom.

§ *f.* Thus, in lat. 71°, 60' of long. = 19.5 miles.

§ 601. When a ship sails due east, or west, she sails either upon a parallel of lat., or upon the equator, and the whole distance sailed is dep.; which may be converted into diff. long. by the formula § *f.* (§ 566.), or by means of the diagram (Plate I.), or Table V.; either of the two latter means is most convenient in practice.

§ 602. When a ship sails due North or South, she sails upon the arc of a meridian, and the whole distance sailed is diff. lat.

§ 603. It is frequently the case, that a ship sails during the day, on more courses than one, making a zig-zag track.

§ *a.* In such cases, it would be a very tedious operation, after finding the diff. lat. and dep. for every course and distance, to convert the dep. for every such course and dist. into diff. long. by a separate operation.

§ *b.* Such circuitry is avoided by taking the whole amount of dep., and converting it into diff. long. by a single inspection of the diagram, or of Table V.

§ 604. Suppose a ship sails from lat. 64° N., 216 miles N.E. by N.; she makes 120 miles of dep. and 179.6, say 180 or 3° diff. lat.

§ *a.* Now this dep., or the diff. long. is not all made upon the parallel of 64°, '5°, '6°, or '7°; or upon any one of the intermediate parallels, but upon all of them together.

§ *b.* And in order to convert, by a single operation, this dep. into long., and to find the diff. long. which the ship has made by sailing this course and distance, the whole dep. is supposed to be

made upon that parallel ($65^{\circ} 30'$) which is midway between the lat. left (64°), and that (67°) arrived at.

§ c. This lat. ($65^{\circ} 30'$) is called the *middle latitude*; it is *half the diff. lat. added to lat. left*; or to that arrived at, if the latter be the less lat.

§ 605. If the number of miles in a degree of long. on the different parallels, as you approach the poles, decreased, as the miles from the equator to those parallels increase, this method would show the true diff. long.

§ a. But the number of miles in a degree of long. at different parallels, is (§ 590. § c.) as the cosines of the lat. of such parallels.

§ b. Wherefore, the result given by this method is only an approximate one.

§ c. But in working up "dead reckoning," "days' works," etc., this method is generally used; it is used in all cases, except in the computation of great distances.

§ 606. On ship-board at the expiration of every hour, sometimes of every two hours, the course and distance sailed during that time are marked opposite each other, on the *log slate*.

§ a. And at the end of every sea day, or at every noon, the courses and distances sailed in the last 24 hours, are "taken off," for the purpose of "working up;" and the whole distance sailed on every separate course is set down, opposite to that course, in a *traverse table*.

Plate 1. } § b. The diff. lat. and the dep. for every course and dist., are taken, either from the diagram, or from Table IV., and set down opposite to their proper course and dist. in the "traverse table."

§ c. The dep. and diff. lat. for every course and dist., are then added up; the sums show the whole dep. and diff. lat.

§ d. And by means of the whole dep. and diff. lat., the course and dist. "made good," are found on the diagram (§ 577. § a.), or are taken from Table IV. or V.

§ e. The "middle lat." (604. § c.) is then found; and by means of it and the dep., the diff. long. is found (§ 594.) on the diagram, or in Table V.

Fig. A.

Course.	Dist.	Diff. Lat.		Depart.	
		N.	S.	E.	W.
N. by E.	20	19.6	--	3.9	--
S. W.	12	--	8.5	--	8.5

§ 607. Fig. A is the formula of a "traverse table."

§ a. The diff. lat. is written in the column marked N. or S. according as the course has *northing*, or *southing* in it. Thus, the diff. lat. for 20 miles N. by E. is put in the N. column, and the diff. lat. for 12 miles S. W. is written in the S. column.

§ b. The dep. must be placed in the column E. or W., according as the course has *easting*, or *westing* in

it. Thus the dep. for the dist. 20 N. by E., is written in the E. column, and the dep. for the dist. 12, S.W. is written in the W. column.

§ 608. The dep. and diff. lat. for any dist. less than 300 miles, and for any course, are found in Table IV., in a manner similar to that by which they are found on the diagram.

§ a. If the course be less than 4 Points, it is to be found at the top of the page, and the diff. lat. must be taken from the column marked at the top (d. lat.), and over which the course is found.

§ b. Thus, to take from Table IV. the dep. and diff. lat. for 120 miles S. $\frac{1}{2}$ E.; find S. $\frac{1}{2}$ E. at the top of the page, and 120 in the dist. column; then in the two columns, at the head of which S. $\frac{1}{2}$ E. is found, and opposite to 120, are the diff. lat. 119.4, and the dep. 11.8.

§ c. But if the course be more than 4 Points, it is to be found at the bottom of the page, and the precept at the foot of the column must be the guide for taking out dep. and diff. lat.

§ d. Thus to take from Table IV. the dep. and diff. lat. for 30 miles E.N.E.; find E.N.E. at the bottom of the page, and 30 in the dist. column, then in the two columns, at the foot of which E.N.E. is found, are 27.7 (dep.) and 11.5 (diff. lat.) opposite to 30.

§ e. If the dist. exceed 300 miles, some aliquot part of it is taken as the 2d, 3d, etc., and the dep. and diff. lat. opposite to this quotient being increased by 2, 3, etc., as much as the dist. was reduced, give the required dep. and diff. lat. Thus to find the dep. and diff. lat. for 400 miles N.N.W.; take 200, the half of it; then, under N.N.W. and opposite 200, stands 184.8 in the d. lat. column, and 76.5 in the dep. do.; each of which being multiplied by 2, gives the required diff. lat. 369.6 or $6^{\circ} 9' 36''$, and the dep. 153 miles.

§ f. Table V. is used in the same way for finding dep., diff. lat., etc., when the course is given in degrees. Thus the dep. for 18 miles N. 30° E. is 9 miles; and the diff. lat. for 40 miles S. 74° E. is 11 miles.

§ 609. The courses in the 1st column of the "traverse table" are the courses sailed per compass.

§ a. Those in the 2d column are those corrected (§ 298. § b.) for variation, which is 1 Point E.

§ b. The diff. lat. and dep. in their columns, answer to the dist. and corrected courses to which they are opposite.

§ d. The diff. lat. 27' 4 S. and the dep. 24.1 E. show that the ship, by sailing the several courses and distances in the table, went to the Southward and Eastward.

§ d. The dep. 24.1 and diff. lat. 27.4 are found opposite 36 (Table V.) and under 42°, which shows the course and dist. "made good," (§ 606. § d.) to be S. 42° E., 36 miles.

§ e. Under 41° (Table V.) 24.1 in the d. lat. column, stands opposite to 32 in the dist. column; the diff. long. then is 32' East.

§ 610. The manner in which "dead reckoning," "days' works," etc., are worked up, and kept at sea, whether by means of the Tables IV. and V., or the diagram, may be learned from the subjoined formulæ. } Plate 1.

§ a. Aug. 28, lat. and long., 62° N. and 47° W.

§ b. Variation W. 1½ Pt., which (§ 298. § b.) is to be allowed towards the left.

§ k. To find the bearing and dist. of Sandy Hook Light House.

S. L. House, lat. 40° 28' N.

Lat. ship - 40° 15' N.

Diff. long. 13'

Long. S. L. House, 74° 1' W.

Long. ship - 73° 12' W.

Diff. long. 49'

49' of long. in lat. 40° is equal to 37.5 miles. (Table V.)

§ l. 13 and 37.5 are found together over 71° (Table V.), and opposite 40. The dist. then of the Light House from the ship, is N. 71° W. 40 miles.

E z

MERCATOR'S SAILING.

§ 611. Dep. : rad. : : diff. long. : sec. lat. (§ 587. § c.). Upon the principles involved in this proportion, the charts, called Mercator's, are constructed.

§ a. In these charts, the meridians of longitude, after they cross the equator, instead of approaching each other, till they reach the parallel of any latitude, in the ratio (§ 486. § b.) of rad. to the cos. of that lat., are drawn parallel to each other.

§ b. And the parallels of lat., say at 1° a part, instead of being at equal distances from each other, are drawn in the ratio of rad. to the sec. of their latitude. By which means, places on a sphere, are represented on a plane with their proper relative positions.

§ 612. In this manner of representing portions of the surface of a sphere upon planes, the parallels of latitude are lengthened out, and the meridians of longitude are expanded.

§ a. So that, if the 1st degree of lat., from the equator, be divided on the chart into 60 equal parts, every degree as they succeed each other in numerical order will contain a greater number of these parts, than the 1st, or than that which precedes it; thus, the 61st of lat. contains 126 of these parts, and the 31st, 70 of the same parts.

§ 613. These parts are called *meridional parts*.

§ a. Table VI. shows the number of meridional parts from the equator to any degree and minute within the parallel of the 84th of lat.

§ b. The number of meridional parts between any two parallels, is called the *meridional diff. lat.* of those parallels.

§ c. Thus, the mer. diff. lat. between $13^\circ 10'$ and $18^\circ 10'$, is 312.

The mer. parts of $18^\circ 10' = 1109$	}	Table VI.
do. $13^\circ 10' = 797$		

Mer. diff. lat. = 312

§ 614. Now, if any section of the earth's surface be represented on a plane projected according to Mercator's plan, the *true* (nearly), instead (§ 550.) of the *approximate*, distance, etc., between any two places, may be determined by *plane* trigonometrical operations.

§ a. To do this, the Mer. diff. lat., as well as the actual diff. lat. between places, must be used.

§ 615. Mercator's sailing is useful to the navigator, chiefly in enabling him to find, by plane trigonometrical calculations, the number of miles between places that are at a great distance from each other.

§ a. The several cases in loxodromic sailing, may also be accurately solved, according to the principles of Mercator's sailing; but the Mer. diff. lat. must be used, as well as the actual diff. lat.

§ b. Methods of applying the principles of Mercator's sailing to the solution of cases in loxodromic sailing, will be shown; but the

application of them to practice, will be left for the amusement of the learner.

§ 616. A B O represents the relative position of Boston and New Orleans in lat. and long., according to the principles of Mercator's sailing.

§ a. And the triangle $a b O$ shows the bearing, dist., etc., according to loxodromic sailing.

§ b. The meridional lat. of Boston is 2813, and that of New Orleans, is 1885 (Table VI.); and the difference between these (§ 613. § b.) is (O A) the Mer. diff. lat.; and A B is the diff. long.; A O B is the course from New Orleans to Boston.

§ c. According to the loxodromic plan of constructing the triangle, $a O$ is the actual diff. lat. between the two places, and $a b$ is the dep.

§ d. Whether the problem proposed be solved according to the loxodromic or Mercator plan, the actual diff. lat. between the two places is the same.

§ e. But the dep. and dist. determined by the former method (§ 550.) are not the true dep. and dist. between the two places.

§ 617. As the angles $a b O$ and A B O (§ 616. § d.) are equal, $a b$ (§ 30. § d.) is parallel to A B; whence (§ 73. § d.) arise the relation between the sides of a triangle in loxodromic sailing when compared with the sides of a similar triangle in Mercator's sailing.

§ a. Diff. lat. : dep. : : Mer. diff. lat. : diff. long.; also inversely and alternately.

§ b. The relations between the other parts of the two triangles may be established according to the principles derived from § 72. & § 73. The learner may arrange them.

§ 618. If the Mer. diff. of lat. (O A) between New Orleans and Boston be made radius, several sets of proportions (§ 75.) will appear among the different parts of the triangle involved.

MERCATOR'S SAILING.

§ a. But the most useful proportion (and in fact almost the only one which occurs in practice), in Mercator's sailing, is that by which the *true* course and dist. between any two places are evolved. I shall give the terms of this proportion, and leave the others to be arranged by the learner.

§ 619. The Mer. diff. lat. (§ 618:) being radius ; Mer. diff. lat. : rad. :: diff. long. : tang. course.

§ a. The diff. long. thus used, must in all cases be converted into minutes, which must be used in the log. Table of Numbers, as miles.

§ b. To find the course from New Orleans to Boston.

Boston	lat.	42° 23'	M. pts.	=2813
N. Orleans	"	29° 57'	"	1885
		12° 26'	"	
		60	"	928 = Mer. diff. lat.

Diff. lat. = 746 miles.

N. Orleans,	long.	90° 9' W.
Boston	"	71° 4' W.
		19° 5'
		60

Diff. long. = 1145 minutes (').

Now, (§ 619.) 928 : rad. :: 1145 : tang. course.

928	log. (Ar. co.)	=7.032452
1145	log. (§ b.)	=3.058806

Tang. course = 0.091258 N. 50° 58' 34" E.

§ c. Then calling O A, the actual diff. lat., A B becomes dep., and retaining O A, as rad., we have (§ 574. § d.) rad. : diff. lat. :: sec. course : dist.

Diff. lat. 746 miles log.=2.872739
 Course N. 50° 58' 34" E. sec.=0.200906

Log. dist.=3.073645=1184.8 miles.

§ d. Problems in Mercator's sailing may also be solved either by Tables IV. & V., or by the diagram (Plate 1). Thus the mer. diff. lat., and the diff. long., being used on the diagram, or in the tables as diff. lat. and dep., show the course. Then with this course the dist. is found opposite to the actual diff. lat.

§ e. Philadelphia lat.	39° 57' N.	M. parts	- 2610
Washington city lat.	38° 53' N.	"	- 2536
	1° 4'	M. diff. lat.=	83
	60		60

Diff. lat.=64 miles.

Washington long.	77° 2' W.
Philadelphia "	75° 9' W.

1° 53'
60

Diff. long.=113 minutes (').

113 in the dep. column stands opposite to 83 in the d. lat. column; (Table V.) 54° is at the bottom of the page. The course then from Philadelphia to Washington is S. 54° W. On the same page 64 in the d. lat. column stands opposite to 109 miles, which is the dist. between the two places.

SURVEYING.

§ 620. In conducting the survey of a coast, harbour, etc., the first object should be to ascertain the geographical position of some point connected with the survey, and the next to establish a *base line*.

§ 621. The most advantageous location for the base line, must be determined by the surveyor himself; and in this, he should be governed by circumstances, such as the nature of the ground about the place to be surveyed, and the place itself.

§ a. A level piece of ground should be selected for the base line, and the line should terminate at points, whence some of the prominent points, headlands, etc., of the place (say a harbour) under survey can be seen.

§ 622. The length of the base line must be ascertained by actual measurement, and the direction in which it lies must be established by observations, and noted down.

§ a. Then, knowing the length of the base line, it serves as a

given side of a triangle, either for determining the length of other lines, or for finding the distance between either end of it, and any point visible from each end of the base.

§ *b*. For if the bearing of such point be taken from each end of the base, a triangle may be formed, in which the angles and the base are known, wherefore (§ 106. § *a*.) the two sides are determinable.

Plate 9. { § 623. The figure in the annexed plate is the *profile* of a harbour, that is being surveyed. A B is the base line, A C B, A D B, etc., are triangles constructed upon it; the angles at A, B, C, D, etc., are measured with a sextant or a theodolite, and the length of the lines B D, B C, A C, etc., is determined by trigonometrical calculation. The principal triangles used, are represented by the broken lines A X, A D, etc.

§ *a*. So that triangles may be constructed from one line to another, until sufficient data are obtained for determining, by trigonometrical calculation, the position of every point of the survey.

§ *b*. The line (X Y) of verification is determined, as to its length, both by trigonometrical calculation, and by measurement, in order to establish the accuracy of the survey.

§ 624. The position of the prominent points C, D, E, F, etc., is determined to a greater degree of nicety in this way, than it can be by taking cross bearings, etc., and the intersection of lines.

§ 625. After the *triangulation* of the survey is completed, and the points C, D, E, F, etc., are laid down upon the chart to the requisite scale; the intermediate spaces, G L, L H, etc., of the shore, may be filled up by the eye. A little practice will enable one to sketch these intermediate spaces with all necessary accuracy.

§ *a*. The position though, of every prominent point, such as light houses, rocks, hills, castles, etc., should be established by actual calculation.

§ *b*. In taking the angles, all the angles of every triangle should be measured whenever it can be done. This affords one means of detecting errors during the work of triangulating; for if the sum (§ 32.) of the three angles of a triangle be not 180° according to the measurement, an error is known to exist.

§ *c*. Also the sum of all the angles around the same point (§ 26.) should be 360° ; and, the sum of all the angles which lie within any measured angle, should be equal (§ 24. § *d*.) to the whole angle.

§ 626. After the work of triangulation is completed, or when it is temporarily suspended, the trigonometrical calculations for the part already triangulated, may be made.

§ 627. The soundings of the harbour should be accurately taken, and correctly laid down upon the chart.

§ *b*. The most practicable way of doing this, is to take a row boat, which will pull equal distances in equal times; establish the position of the point from which she sets out, and let her pull directly for a given point, sounding and noting the soundings at every interval of one, two, three, or more, minutes, as she goes along. When

she arrives at the end of this line, establish the position of this end also, draw the line on the chart, divide it into as many equal parts as there were soundings taken, and write along the line every one at its proper point.

§ *b*. The surest way of making a straight course in the boat, is to bring two points on shore in the same line of bearing, and then pull for them, keeping them in that line. For instance; a boat at *a*, would pull in a straight line to *E*, if she kept a tree, or a steeple, or any object at *b*, in a line with *E*; then the soundings taken would all be on the line *a E*; and the position at *a* being determined; taking the angles *B a E* & *E B a*, the length of *a E* may be known, and the soundings laid down.

§ 628. The soundings should be given for low water; wherefore the time of the tide when the soundings are being taken, should be noted, in order to correct them for low water.

§ *a*. The corrections to be applied may be obtained, either according to the rate of the rise and fall of the tide, as established by previous observation, or by means of a figure (§ *e*.), thus;

§ *b*. Say that the rise and fall of the tide is 8 feet, and that the flood tide lasts $5\frac{1}{2}$ hours, and the ebb, 7.

§ *c*. Let the diameter of a circle be divided into 8 equal parts, by the chords 1, 2, 3, etc. Also let one semicircumference of this circle be divided into $V\frac{1}{2}$ equal parts or hours, to represent the time of flooding; and let the other semicircumference be divided into VII. equal arcs to represent the hours during ebb.

§ *d*. The point in which each of these chords cuts the circle, shows the correction in feet which is to be applied, when the tide is that number of hours, flood or ebb. Thus, when the tide is $III\frac{1}{2}$ flood, the correction to be applied is $4\frac{1}{2}$ feet; and when the tide is III. hours ebb, the correction is 5 feet.*

§ *e*.

* These corrections are always subtractive.

§ 629. The sort of bottom should also be noted down, i. e. mud, rock, sand, etc.

§ 630. The position, extent, etc., of all the hidden dangers, such as rocks, reefs, shoals, banks, and of every other object of importance to the navigator, should be ascertained and laid down.

§ 631. Surveys of harbours are frequently taken by measuring first, a base line, then drawing this line upon the paper at the proportional length to the scale upon which the chart is to be constructed, and then establishing the position of the principal points in the survey, by the intersection of the lines of their bearing from different points.

§ a. But the difficulty of measuring with accuracy the proper angles upon paper, makes this method of taking a survey more liable to inaccuracies, than the triangulating plan.

MAURY'S NAVIGATION.

AN ELEMENTARY, PRACTICAL, AND THEORETICAL TREATISE ON NAVIGATION: WITH A NEW AND EASY PLAN FOR FINDING DIFF. LAT., DEP., COURSE, AND DISTANCE BY PROJECTION. BY M. F. MAURY, LIEUT., U. S. NAVY.

OPINIONS OF NAVIGATORS AND PROFESSORS.

Boston, April 21st, 1835.

A work of the kind you are preparing for the press, containing the demonstrations of the formulas of Nautical Astronomy, would be very useful to those who have a taste for the subject, and would like to examine the demonstrations of the rules.

Respectfully,

Your obedient servant,
N. BOWDITCH.

PHILADELPHIA, 14th April, 1835.

DEAR SIR:

I have examined, with as much care as the nature of my engagements has permitted, the book intended for the instruction of the younger officers of the navy, which you have left with me. My opinion is, that such a work will be valuable to them, and will meet with favour among them; supplying, as it does, the mathematical principles involved in the studies of their profession in a sufficiently condensed form.

Coming from one of their own profession, especially, I should anticipate that the work would be received among them, even without the injunction of the authorities, who would, however, I think, find it to the interest of the service to sanction it.

Allow me to say, that I consider the work fully to sustain the high character for scientific acquirement, which I have always heard attributed to its author.

Respectfully yours,

A. D. BACHE, Prof., &c.

The undersigned are of opinion that the work of Lieutenant M. F. Maury, on Navigation, is eminently useful as a school book for nautical students. It illustrates with clearness and simplicity, the principles on which the calculations in navigation are founded.

We felt the want of just such a book in aid of our early studies, and cheerfully recommend it to all who desire to inform themselves in this branch of education, with a view to the nautical profession.

FRANCIS H. GREGORY, Capt.
ROBERT F. STOCKTON, Capt.
FREDERICK ENGLE, Com.
G. A. MAGRUDER, Com.

MY DEAR SIR:

I have great pleasure in stating my belief that it is of the utmost importance that the midshipmen of the navy should have some established work, containing within itself all the information on mathematics and navigation, including nautical astronomy, which they are required to know in order to pass an examination for promo-

mentary, and embrace arithmetic, algebra, geometry, and plane and spherical trigonometry, so far, and so far only, as might be necessary to the construction of all the rules and formulæ requisite to solve the various problems in navigation and surveying. When I was preparing for examination, I felt an earnest desire to possess this information, and to ascend step by step to a complete understanding of the whole subject, so as to have the means of reaching all the processes of which I availed myself by my own resources, without taking any thing on trust. After my promotion I devoted my whole time and attention, for a considerable period, in attaining this object; and feeling how much my own course had been impeded by the want of books containing the required knowledge, I carefully preserved all that I had recourse to for the purpose; such as La Croix, Bezout, Légendre, Lassalle, Borda, and Callet, and determined at my earliest leisure to compile from them a treatise, narrowed down to what was indispensable, so as to spare others, ambitious of more complete information on this branch of professional knowledge than is usual, the great difficulty I had experienced in knowing where to apply for information. The appearance of your work, so exactly supplying what was needed, and, from your infinitely higher mathematical attainments, executed in so superior a manner, to what it would have been had the task been left to me, took from me all motive and desire to go on with the undertaking. After having exerted such commendable exertion, ingenuity, and judgment in accomplishing your task, I trust you may, at least, have the satisfaction of seeing your work generally used by the midshipmen, if not as a manual of practical navigation, which Bowditch's admirable work so effectually supplies, at least as an elementary treatise for the instruction of the young officers of the navy, the more acceptable and encouraging for having been supplied by one, who was, at the time, of their number.

Believe me, very truly,

And respectfully yours,

ALEX. SLIDELL MACKENZIE,
Commander, U. S. Navy.

TARRANTS, 14th November, 1843.

I should not hesitate to commend Maury's Navigation for the use of the midshipmen of our navy. To those of them who are advanced in the elements of the science, it supplies the practical information necessary to make them good navigators; others, who have commenced with

of the principles are both ample, easy, and well arranged.

The work, I know, originated in the wants of the students of navigation on board ships, and I confidently believe that it will supply those wants.

L. M. POWELL,
Commander, U. S. Navy.

U. S. NAVY YARD, GOSFORD, }
8th January, 1839. }

SIR:

I am much pleased with your "Treatise on Navigation." The mathematical investigations it affords of the principles of the science, particularly of nautical astronomy, place it upon different grounds from the treatises upon the subject in common use, and adapt it much better to the purpose of instruction. I am desirous of introducing it, as far as may be practicable, among my own classes; and recommend it to all the younger officers in our naval service, who desire to become acquainted with the theory, as well as the practice of the mathematical part of their profession. Its designation as one of the books to be used in their examination, would, I think, conduce to elevate the standard of mathematical attainments among them.

With great regard,
Your obedient servant.

JOHN H. C. COFFIN.
Prof. of Mathematics, U. S. Navy.

WASHINGTON, 20th Dec., 1842.

DEAR SIR:

I have been much interested in a hasty examination of your work upon *Navigation*, more particularly with that part of it, which relates to "Spherical Trigonometry," and "Nautical Astronomy," two branches of navigation that have been too superficially treated in the most popular works upon the subject, to answer the increasing general information of the practical navigators of the present day.

During the last forty years, but little improvement of this kind has been introduced into the standard works upon navigation, and as a general remark, it may be safely asserted that they are behind the wants of those who use them.

Ever anxious for the general diffusion of such important knowledge in our profession, I trust you will be encouraged to introduce the work into the navy as a *Text-Book*. I remain, respectfully, etc.,

JAMES GLYNN,
Commander, U. S. Navy.
Lt. M. F. MAURY, U. S. N.

U. S. SHIP DALE, 23d Oct., 1843.

I feel great pleasure in recommending Maury's *Navigation* as a work of real usefulness and importance to the young officers of our navy.

It embodies whatever can be of utility to the navigator, in a concise and perspicuous manner; and its explanations and references calculated to excite, in youthful and inquisitive minds, a desire for the higher attainments. Having used

the work myself, I know its value, and, therefore, hope it will become the authorized book of study for the midshipmen of our navy.

THOS. A. DORNIN,
Commander, U. S. Navy.

FLAG SHIP PENNSYLVANIA, }
November 4th, 1843. }

MY DEAR SIR:

I have, with great pleasure and care, examined your book on *Navigation*, and do decidedly recommend and prefer it to any other in use. The mathematical principles condensed in such a form, is a sufficient recommendation to every student of navigation, and I recommend it to all mathematicians and young officers belonging to, and at schools attached to the navy, and should think that the Hon. Secretary of the Navy would so order it.

I have the pleasure to remain, with regard,
Your obedient servant,
E. P. KENNEDY,
Lt. M. F. MAURY, U. S. N. P. C., Norfolk.

U. S. SHIP PENNSYLVANIA, }
Nov. 3d, 1843. }

SIR:

I have been much gratified in the perusal of your *Treatise on Navigation*; and think it well adapted for use as a school book, and one best calculated, of any that I have seen, to induce a love for the prosecution of the study of navigation as a science, and not merely as an art.

I am, very respectfully,
Your obedient servant,
A. G. PENDLETON,
Prof. of Mathematics, U. S. Navy.
Lt. M. F. MAURY, U. S. N.

U. S. SHIP OHIO, BOSTON, }
Nov. 14th, 1843. }

SIR:

I have examined, with a good deal of attention, your *Treatise on Navigation*, and find it embraces all the elements necessary to constitute a scientific navigator. It would, I believe, be found a valuable auxiliary in our naval schools.

The work of Dr. Bowditch, although eminently useful as a *practical* one, fails almost entirely in the development of the principles from which its rules are derived.

It seems, therefore, desirable, that some work explaining more fully the *theory* of navigation should be put into the hands of our midshipmen, in order that they may become, as we all desire, *scientific*, as well as *practical* navigators.

Hoping that the pleasure of furnishing such a work for the younger officers of the service may be yours,

I remain, very respectfully,
Your obedient servant,
JOS. T. HUSTON,
Prof. of Mathematics, U. S. Navy.
Lt. M. F. MAURY, U. S. N.

U. S. SHIP BOSTON, BOSTON, }
Nov. 15th, 1843. }

DEAR SIR:

I am much pleased to learn, through the

Army and Navy Chronicle, that a new edition of your valuable Navigator is soon to be published.

I cannot doubt the success of a large second edition, and I am confident that it will add to your reputation, and secure for your book the celebrity which it deserves. Its merit is recognised in the navy, and I would recommend it in all schools of navigation, particularly on account of the manner in which many difficult and obscure points are made easy and plain.

Respectfully, etc.,

G. J. PENDERGRAST.

Commander U. S. Navy.

Lt. M. F. MAURY, U. S. Navy.

WILMINGTON, Del. Nov. 5th, 1843.

I consider Maury's Treatise on Navigation, the very work that has long been wanting in our schools, and I hope it will eventually be used in all of them (particularly the naval ones) instead of Bowditch's Practical Navigator; for I think it far superior as a book of instruction.

J. SHUBRICK,

Commander, U. S. N.

NORFOLK, Nov. 7th, 1843.

I think Maury's Navigation is admirably adapted for the instruction of the young officers of the Navy. All the problems are deduced from theorems, in such a manner as to give the young seaman a correct idea of the theory as well as the practice of navigation. The methods are simple and accurate, and the tables well and carefully constructed. The work contains all that the student of navigation can require; and were it made the authorized text book of the Navy, the standard of mathematical attainments among midshipmen, would be greatly elevated.

R. B. CUNNINGHAM.

Commander, U. S. Navy.

NOVEMBER 8th, 1843.

I possess a copy of Maury's Navigation, and consider it a valuable text-book for all nautical students, whether in the United States Naval Service, or in the commercial marine.

The author, Lieutenant M. F. Maury, U. S. Navy, is a man of science, and has produced this work under the advantage of knowing from experience what the nautical student and practical navigator require.

S. P. LEE,

Lt. U. S. Navy.

U. S. NAVAL HOSPITAL, }
New York, Nov. 10th, 1843. }

SIR:

Your volume seems to me well calculated to achieve the object for which it seems designed: namely, to demonstrate the formulas of Nautical Astronomy, and explain the principles upon which the art of navigation is founded. A better book for schools of navigation, than yours, I am persuaded does not exist in our language. But

after the expression of favourable opinions of it, by such men as Bowditch, Alexander Dallas Bache, P. J. Rodriguez, Edward C. Ward, and John H. C. Coffin, all eminently qualified to judge of such a work, few can doubt its worth or set any value upon the opinion of,

Very respectfully,

Your obedient servant.

W. S. W. RUSCHENBERGER,

Surgeon, U. S. N.

Lieut. M. F. MAURY, U. S. Navy.

U. S. SHIP CUMBERLAND, }
Boston, Nov. 14th, 1843. }

DEAR SIR:

From the cursory examination I have given your treatise on navigation, I, for one, am proud that so useful and valuable a work has been furnished by one of our own corps.

With the improvements you propose to add in the new edition you are preparing, I doubt not it will possess advantages over other works of the kind, and be found a valuable auxiliary in our naval schools.

Very truly yours,

JOSEPH SMITH,

Captain U. S. Navy.

Lieut. M. F. MAURY, U. S. Navy.

WASHINGTON CITY, Nov. 23d, 1843.

DEAR MAURY,

I take this occasion to express to you the pleasure I feel, in noticing the announcement of a new edition of your treatise on navigation. Its subject matter being strictly professional, has called for the close scan of many of your brother officers, myself of the number. Its worthiness to become the text book of our young naval officers, may, with propriety, be judged of by those who are called on to exhibit a certificate of having been closely examined on, and found to possess a thorough knowledge of the subject treated of in your book alluded to.

Without an exception, all of our brother officers, and they are many whom I have heard descant freely on the merits of your work on navigation, pronounced it to be the best text book on that subject extant. In a full concurrence with that opinion,

I am with much esteem,

Respectfully yours truly,

WM. W. HUNTER,

Lieut. U. S. Navy.

Lieut. M. F. MAURY, U. S. Navy.

U. S. BRIG PERRY, }
Norfolk, Va., Nov. 24th, 1843. }

DEAR SIR:

I am pleased to learn you are preparing an improved edition of your Navigation, more especially with the view of instructing the midshipmen in the theory of navigation. To carry the student beyond the mechanical solution of nautical problems, into a comprehension of those principles of Mathematics and Astronomy, upon which these problems are based, seems to be wanting in most treatises on Navigation.

Even Dr. Bowditch's invaluable epitome, that has laid every American, who has to trace his way on the great deep, under a lasting debt of gratitude, is wholly practical in its method. But the value of a Class Book proposing to teach the young officer the theory of one branch of his profession, which imbues his mind with some tincture of science, and raises him above the blind worker of mechanical problems, need not be enlarged upon; though it cannot be better appreciated than by those in the profession, who were deprived of the many advantages now offered to our midshipmen, and who were compelled to prepare for their examination with a Practical Navigator for their sole instructor, and a camp-stool between two guns, for their study room.

Uniformity in instruction too is a matter of great importance, and not doubting that the superior authority, who alone can prescribe the book to be taught, will fully appreciate the honorable contribution afforded by your work, to the character and benefit of the Navy, and that it will be made the standard at the examination of midshipmen,

I remain, my dear sir,
Very sincerely, &c.
S. F. DUFOUR,
Commander, U. S. N.

Lieut. M. F. MAURY, U. S. Navy.

St. AUGUSTINE, FL. FLORIDA,
Nov. 27th, 1843. }

My opinion can contribute nothing to the established reputation of your valuable work. I can only say, that when I first looked through it, I considered it as thoroughly supplying the great desideratum of a midshipman's study of navigation, and remarked to those who were present, "How unfortunate were we, in not having such a book when we were students of navigation." My opinion has been confirmed by that of other and more competent judges, and I believe that throughout the entire service, there has not been a disparaging voice raised against it. I regard it as being to Bowditch what Bowditch was to Hamilton Moore.

Respectfully, &c.
WM. F. LYNCH,
Lieut. U. S. Navy.

Lieut. M. F. MAURY.

YALE COLLEGE, CONN.
October 26th, 1843. }

This valuable work on Navigation, theoretical and practical, it seems to me desirable to have placed in the hands of every naval officer, who may have occasion to navigate a ship or to explain the principles of Nautical Astronomy. These are well brought out, and illustrated with examples of their application, which render the treatise clear and intelligible, and adapt it well to the purposes of a text book for learners. This book as a guide in the rationale principles of navigation, and Bowditch's companion in the practical computa-

tions, the young officers of our Navy may be well prepared for the important and responsible duties of navigators. Having formerly used the work at sea, while engaged as an instructor in the naval service of the U. S., I cordially give it this recommendation.

JAMES NOONEY, Jr.
Tutor in Nat. Philosophy,
Late Prof. of Math. U. S. N.

SURVEYING SCHR. GALLATIN, }
Philadelphia, Dec. 13th, 1843. }

DEAR SIR:

I have learnt with pleasure that a second edition of your work on Navigation will shortly be published.

I have always considered this book, from its general arrangement, and the kinds of solution employed, as decidedly the best work for students extant.

Believe me, truly yours,
(Signed) GEO. S. BLAKE,
Lt. M. F. MAURY, U. S. N. Washington.

Opinion of Capt. M'INTOSH, U. S. N. }
New York, Dec. 12th, 1843. }

It affords me great pleasure to state, that I consider your work on Navigation, as one of the very best now extant, and most cheerfully recommend it as most suitable for a school book for midshipmen.

Lieut. MAURY.

Opinion of Capt. PERCIVAL, U. S. N. }
U. S. SHIP CONSTITUTION, }
Gosport, Dec. 14th, 1843. }

In compliance with your request, I have perused Maury's "New Theoretical, and Practical Treatise on Navigation," and have found it, as far as I am able to judge, a convenient reference, in illustrating the principles of Nautical Astronomy. Its explanations of the principles of Spherical Trigonometry, and its application of them to the solutions of the various astronomical problems, so essential in navigation, render it a book, in my opinion, not only useful as a supplement to our first (Bowditch's) standard work on the subject; but valuable in itself: an acquisition to the nautical student, who, if he is desirous of acquiring a correct, and practical knowledge of his profession, may be largely aided by the study thereof.

Lt. M. F. MAURY, U. S. N.

Opinion of Capt. FORREST, U. S. N. }
WASHINGTON, Dec. 18th, 1843. }

I take much pleasure in recommending your "New Theoretical and Practical Treatise on Navigation." The explanations and illustrations are rendered clear and comprehensive, and I believe it to be just such a production as we require for the instruction of the young officers of our Navy, as well as others desirous of obtaining a well grounded and accurate knowledge of the science.

Lt. M. F. MAURY, U. S. N.

*Opinion of the U. S. Naval Lyceum, }
Brooklyn, New York. }
BROOKLYN, Dec. 20th, 1843.*

The undersigned, a committee to which was referred Lieut. Maury's "Treatise on Navigation," report that they have carefully examined the same, and are of opinion that it is a work well adapted for the instruction of the young officers of the Navy, as all the problems and formulæ that are necessary in their profession, are there brought together in a condensed form, and so clearly, and concisely demonstrated, that the student may easily inform himself of the theory and principles on which his practice is founded; and the accompanying tables are so constructed as to facilitate his calculations; all of which are systematically arranged, with a simplicity that has heretofore been generally wanting in works on Navigation. They would therefore recommend the same to be adopted for the use of the Naval schools.

Signed,
J. H. STRINGHAM,
WM. D. NEWMAN,
ALEX. C. GIBSON.

The following opinions have already appeared in print, but as they have in all probability escaped the notice of many to whom these pages will be presented, they are again inserted here.

U. S. N. S., New York, January 19, 1836.

"Dear Sir,—I have had much pleasure in the perusal of your "New Theoretical and Practical Treatise on Navigation;" the plan and arrangements of which are original; it contains little or nothing superfluous, and every part of it appears to be as clear and intelligible as the nature of the subject will admit. Such a work has long been wanted in our Naval Schools, and on board our vessels of war. I intend to make use of it in the Naval School on this station; and I recommend it to be used by all the professors of Mathematics and Nautical Science, in the Navy of the United States.

"Yours Respectfully,

"EDW. C. WARD,

"Prof. Math. U. S. Navy."

"Passed Midshipman M. F. Maury,

"U. S. Navy."

U. S. Navy Yard, Gosport, March 7, 1836.

"I have examined a Treatise on Navigation written by M. F. Maury of the U. S. Navy; and have no hesitation in recommending it to the students of that science. The explanations are clear, the rules are illustrated by many examples, and the new arrangement of some of the tables simplify the calculations of the navigator. Mr. Maury is deserving of great credit for the work, and I wish him every success.

P. J. RODRIGUEZ.
